Zebrafish Behavioral Profiling Links Drugs to Biological Targets and Rest/Wake Regulation

Jason Rihel,[1]*† David A. Prober,[1]*‡ Anthony Arvanites,[2] Kelvin Lam,[2] Steven Zimmerman,[1] Sumin Jang,[1] Stephen J. Haggarty,[3,4,5] David Kokel,[6] Lee L. Rubin,[2] Randall T. Peterson,[3,6,7] Alexander F. Schier[1,2,3,8,9]†

15 JANUARY 2010 VOL 327 SCIENCE

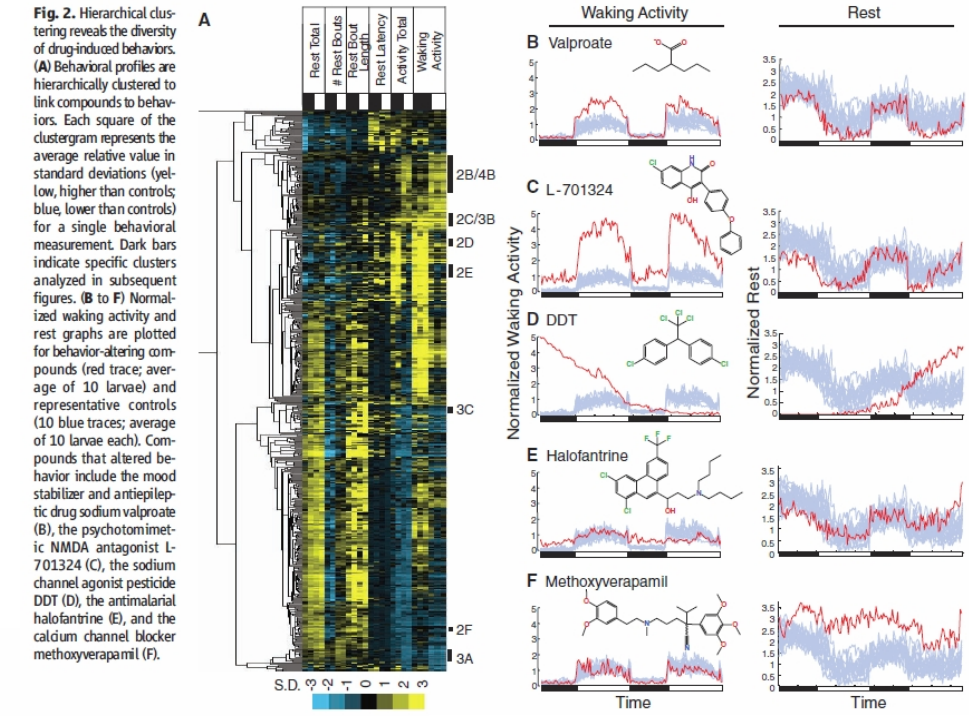

Fig. 2. Hierarchical clustering reveals the diversity of drug-induced behaviors. (**A**) Behavioral profiles are hierarchically clustered to link compounds to behaviors. Each square of the clustergram represents the average relative value in standard deviations (yellow, higher than controls; blue, lower than controls) for a single behavioral measurement. Dark bars indicate specific clusters analyzed in subsequent figures. (**B** to **F**) Normalized waking activity and rest graphs are plotted for behavior-altering compounds (red trace; average of 10 larvae) and representative controls (10 blue traces; average of 10 larvae each). Compounds that altered behavior include the mood stabilizer and antiepileptic drug sodium valproate (B), the psychotomimetic NMDA antagonist L-701324 (C), the sodium channel agonist pesticide DDT (D), the antimalarial halofantrine (E), and the calcium channel blocker methoxyverapamil (F).

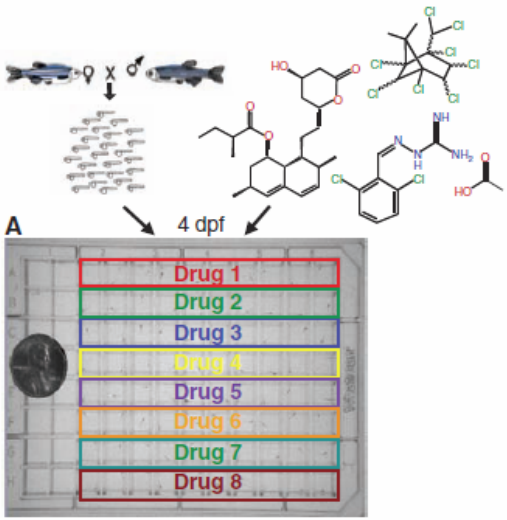

Fig. 1. Larval zebrafish locomotor activity assay. (**A**) At 4 days post-fertilization (dpf), an individual zebrafish larva is pipetted into each well of a 96-well plate with small molecules. Automated analysis software tracks the movement of each larva for 3 days. Each compound is tested on 10 larvae. (**B**) Locomotor activity of a representative larva. The rest and wake dynamics were recorded, including the number and duration of rest bouts [i.e., a continuous minute of inactivity (*8*)], the timing of the first rest bout after a light transition (rest latency), the average waking activity (average activity excluding rest bouts), and the average total activity. Together, these measurements generate a behavioral fingerprint for each compound.

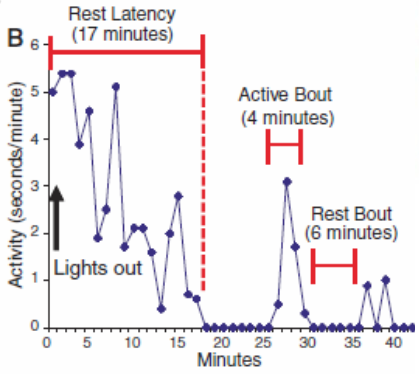
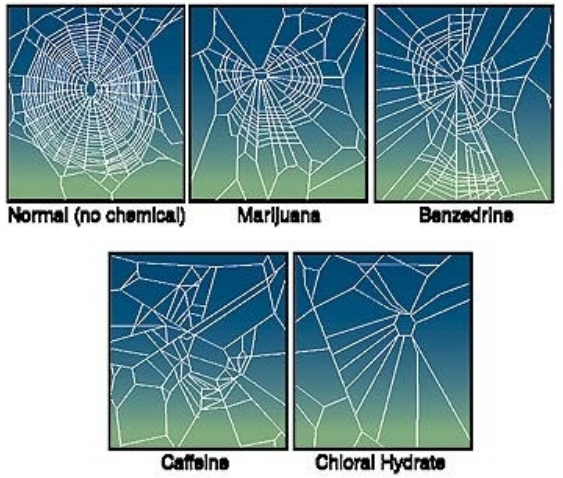
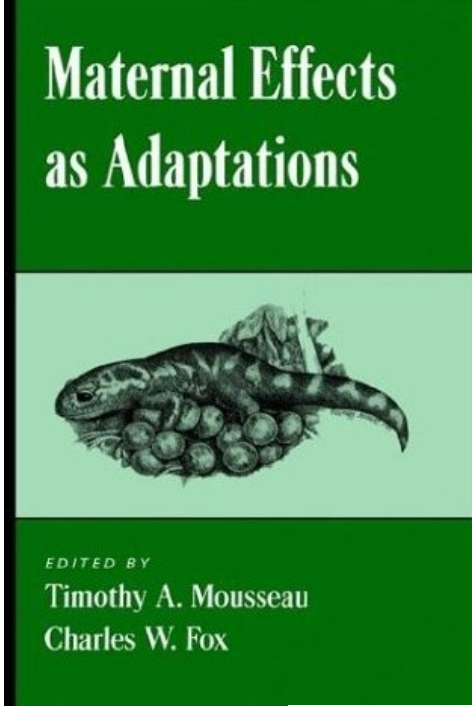




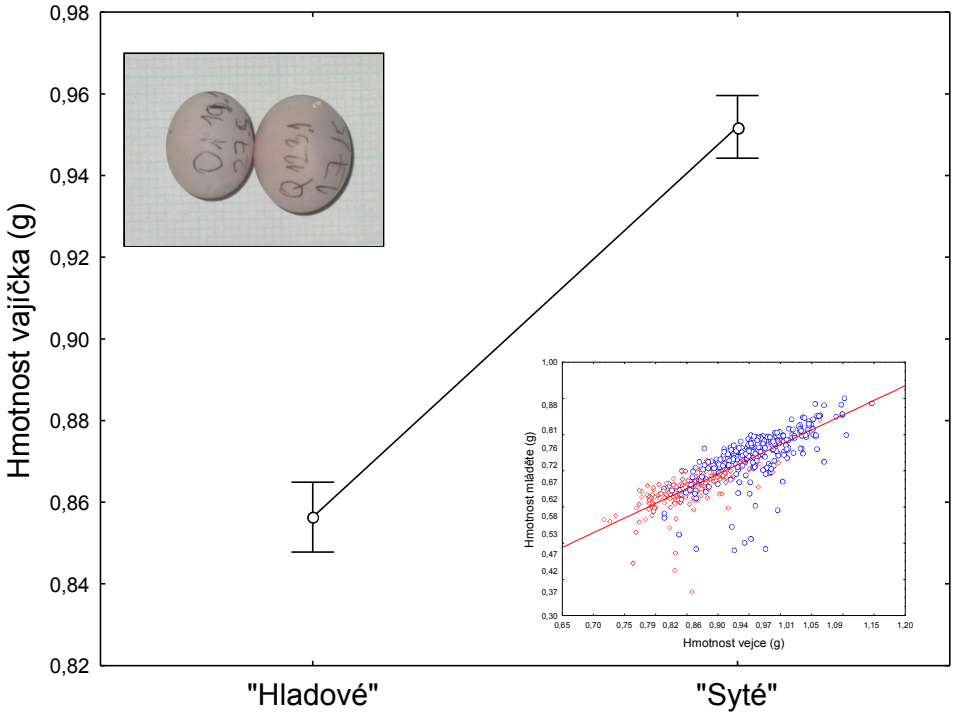


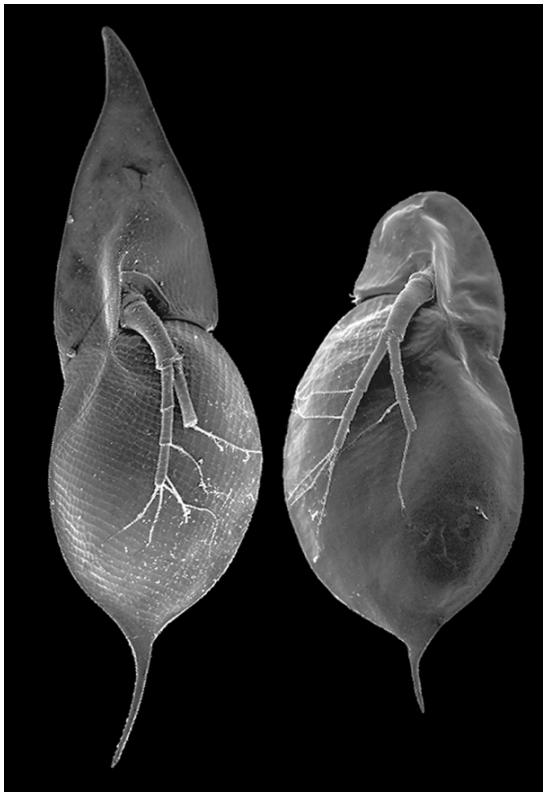
Je fenotypová plasticita adaptivní?

Maternální efekt:

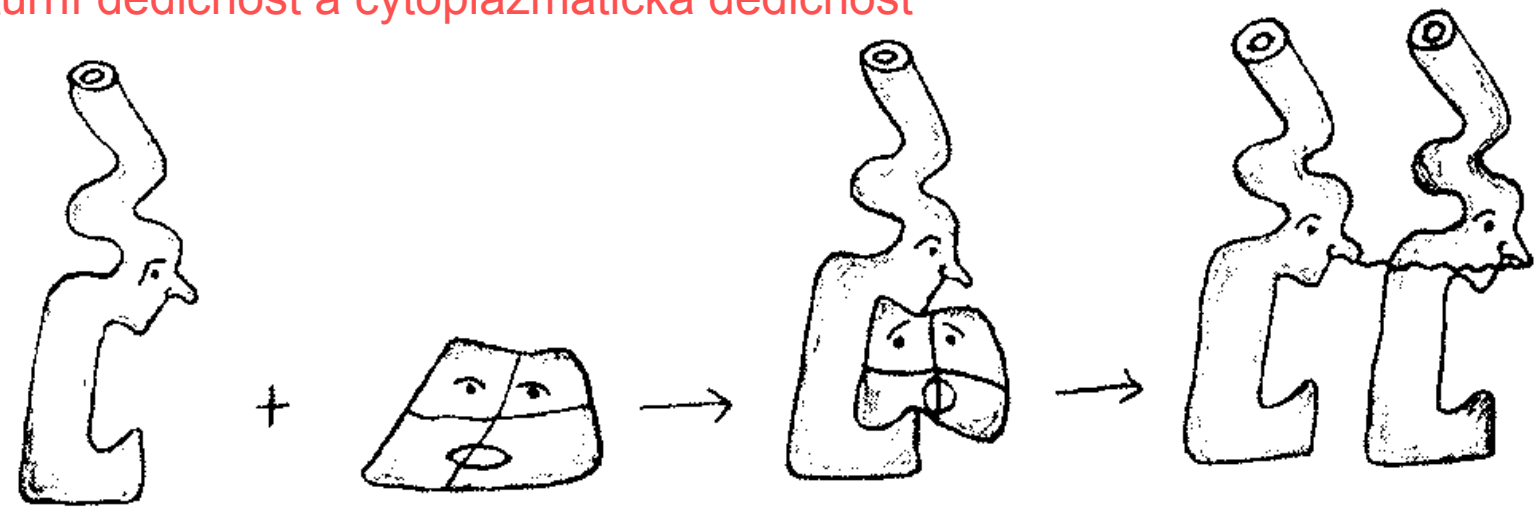
- rodiče optimalizují fenotyp potomků na prostředí, ve kterém sami žili

- jedinci v dobré kondici získané díky prostředí bohatému na zdroje přenášejí dobrou kondici na potomky (ale ta se hodí i ve špatném prostředí) - ostatní dělají „the best of bad jobs“





Strukturní dědičnost a cytoplazmatická dědičnost



Fenotypová plasticita (a maternální efekty) jsou často spojeny s metabolismem steroidních hormonů

Proc. Natl. Acad. Sci. USA

Neurobiology

Yolk is a source of maternal testosterone for developing birds

(egg/steroid hormone/embryo/sexual differentiation/aggression)

HUBERT SCHWABL

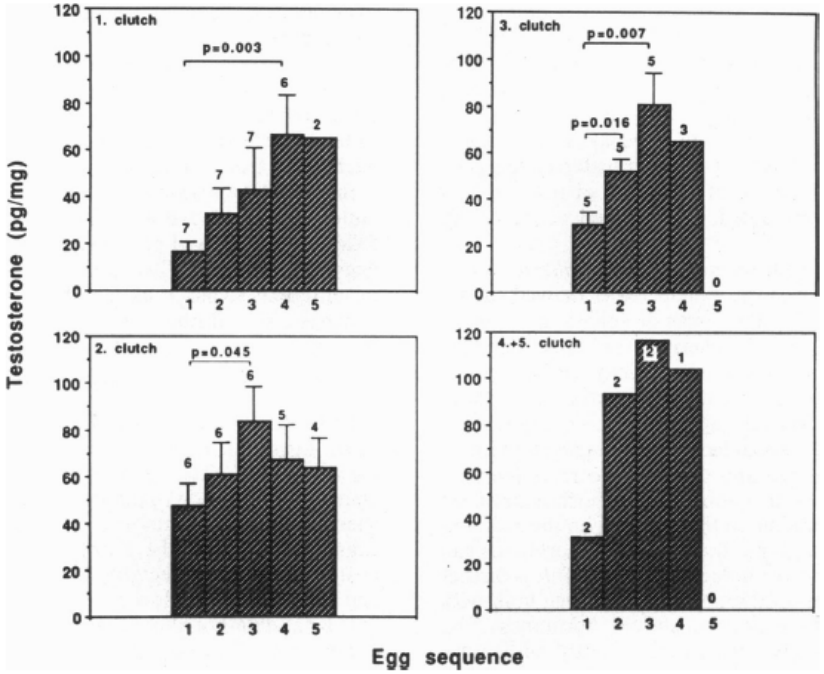

FIG. 2. T concentration (in picograms per mg of yolk; means ± SEM) of eggs from successive clutches laid by seven pairs of canaries, showing the order of laying in a clutch. Numbers on top of columns indicate numbers of eggs. T levels varied with order of laying (clutch 1: $F = 4.92$, $P = 0.019$; clutch 2: $F = 6.71$, $P = 0.011$; clutch 3: $F = 0.69$, $P = 0.54$). Statistical analysis was not done on clutches 4 and 5, here shown together, because of the small number of eggs laid. Significant differences in T contents between eggs are indicated by brackets.

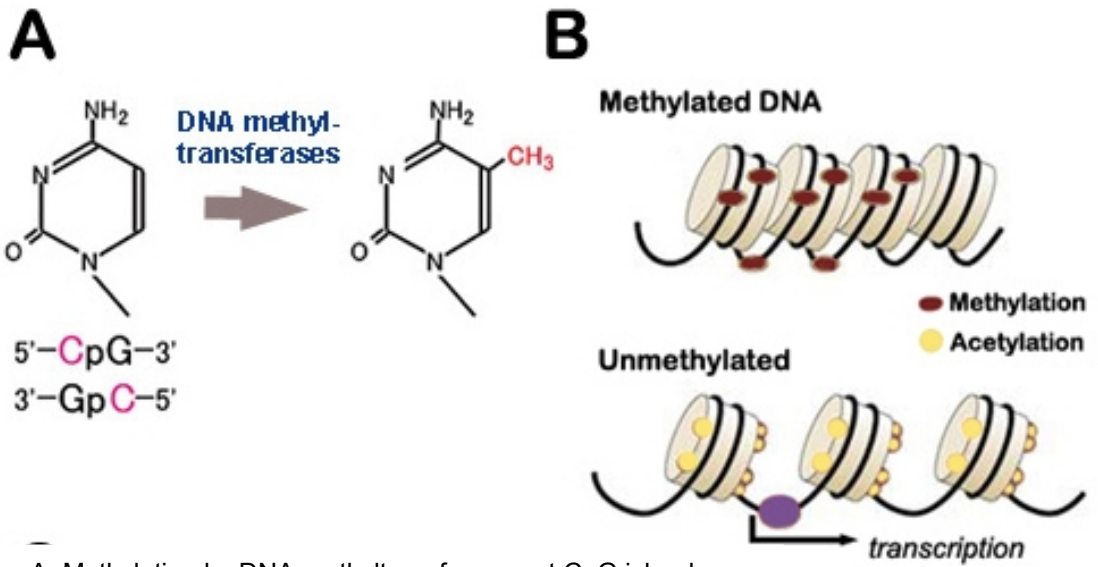
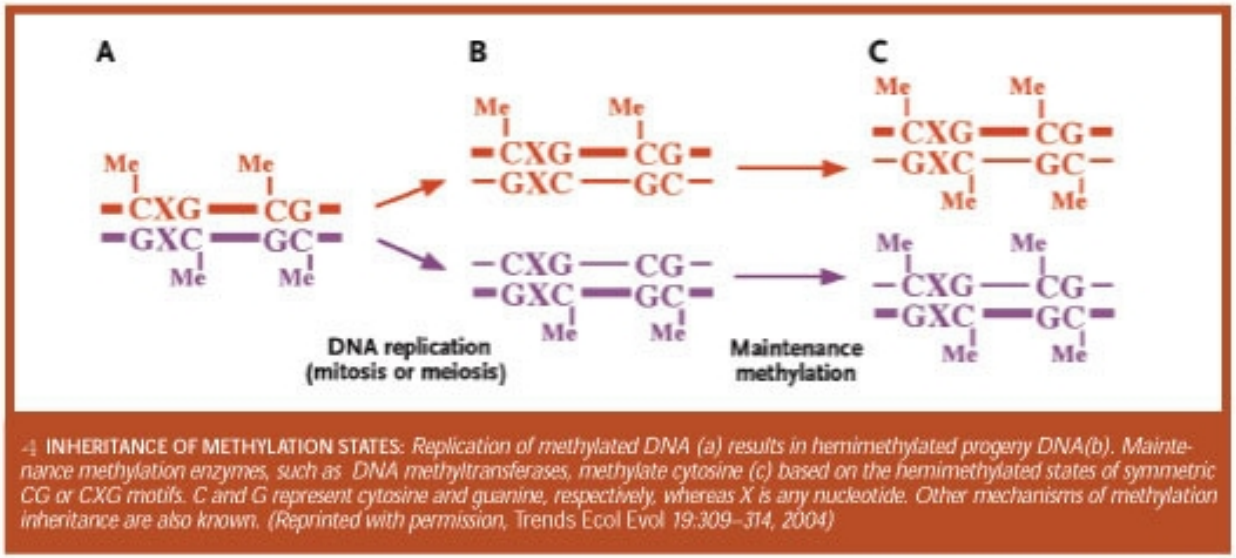
Fenotypová plasticita může souviset s epigenetickými změnami chromatinu



A. Methylation by DNA methyltransferases at CpG islands.
B. DNA demethylation relaxes chromatin structure allowing histone acetylation and the binding of transcriptional complexes.



4 INHERITANCE OF METHYLATION STATES: *Replication of methylated DNA (a) results in hemimethylated progeny DNA(b). Maintenance methylation enzymes, such as DNA methyltransferases, methylate cytosine (c) based on the hemimethylated states of symmetric CG or CXG motifs. C and G represent cytosine and guanine, respectively, whereas X is any nucleotide. Other mechanisms of methylation inheritance are also known. The environmental contribution to gene expression profiles

Greg Gibson

- *cis*-regulace
- *trans*-regulace nebo společná regulační síť

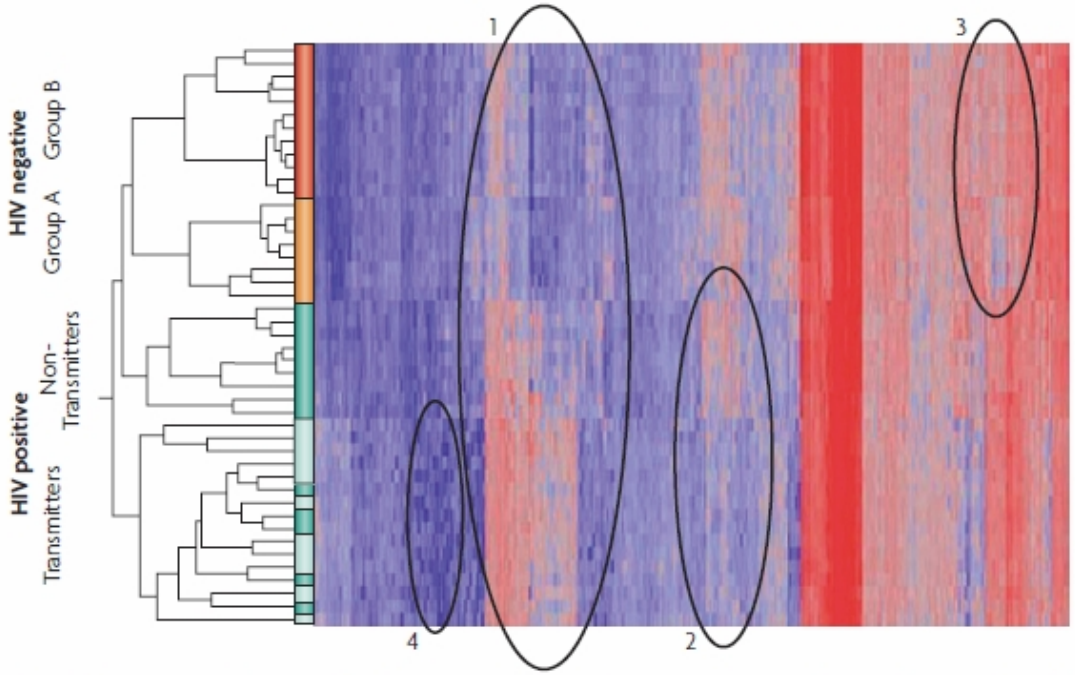

Figure 1 | **Sources of expression heterogeneity.** This heat map shows the expression profiles of several thousand genes that are differentially expressed in a sample of 45 Botswanan women[4]. Each row is the profile of an individual woman, each column represents the abundance of one transcript from very low (dark blue) to low (light blue) to very high (dark red) expression. The clustering suggests four groups, but the analytical challenge is to identify statistically significant groupings of subsets of genes, and to explain the sources of variability. Visually, the genes within ellipse 1 demarcate HIV-positive from HIV-negative women. Those in ellipse 2 identify a subset of non-transmitting mothers (top dark green bar), whose profile is distinct from a group consisting of both mothers who did transmit the virus (top light green bar) and of some of the transmitters (other dark green bars). Ellipse 3 highlights a group of genes that differ in abundance between two subgroups of the HIV-negative women, and ellipse 4 highlights a group of genes that are especially heterogeneous within the transmitting mothers, as implied by the variety in the depth of blue shading. A simple prediction would be that a common *trans*-acting genetic factor produces group 3, because there is clear co-regulation of the transcripts, whereas *cis*-acting genetic factors might independently regulate the transcripts in group 4. Feasibly, joint genotyping and expression profiling can be used to test the hypothesis. Alternatively, numerous loci spread throughout the genome could lead to clustering of relatives, in which case pedigree or relatedness analysis should suggest that individuals with similar expression profiles are more closely related by descent.

Fenotypová plasticita a exprese genů

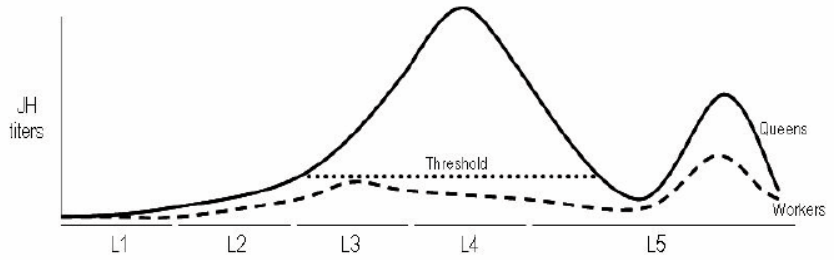

Figure 1
Reaching of the juvenile hormone (JH) threshold in developing females is proposed not only to allow for the general body growth and ovary development, but also to act by negatively regulating the development of some organismal systems that are characteristics of adult workers and are also present in the original developmental pattern. JH titres during larval development (L1–L5) data are modified from Hartfelder and Engels [5]

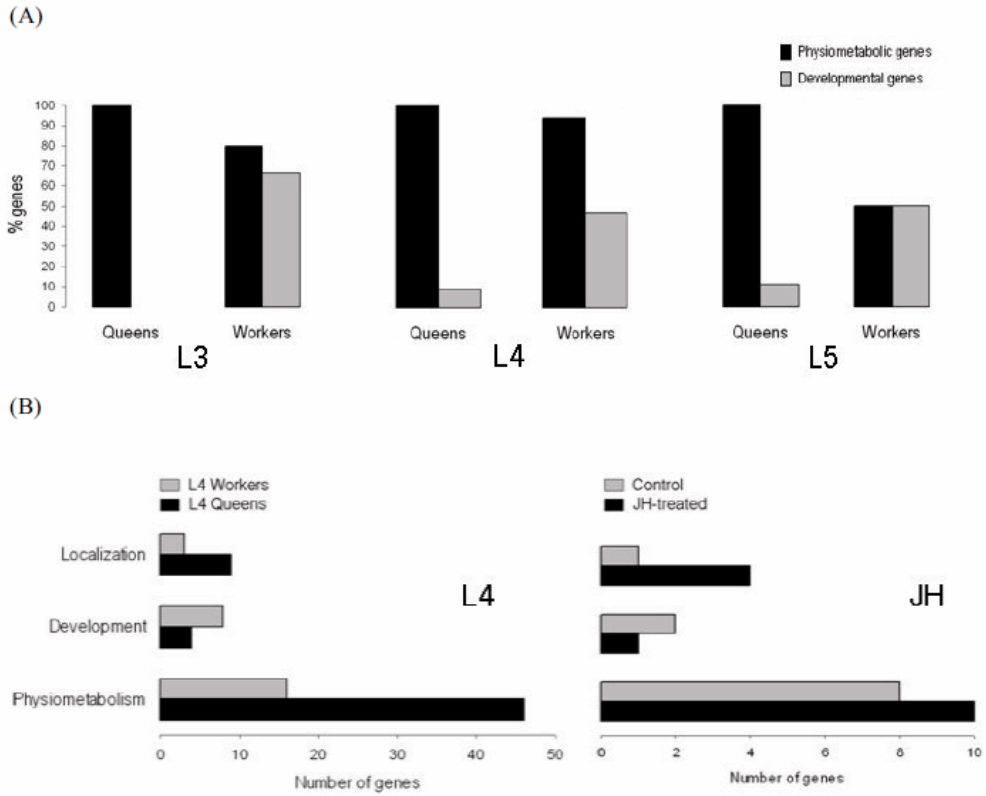

Figure 2
Functional trends of DEGs classified according to the Biological Process terms defined by GO consortium. (A) Developing workers up-regulate more developmental genes than queens in all studied larval instars. Physiometabolic genes are always more up-regulated than developmental genes (B) Juvenile hormone (JH) treatment induces a queen-like gene expression profile. Left panel: up-regulated genes in L4 queens/workers. Right panel: up-regulated genes in L4 Control/JH-treated workers. The proportion of Physiometabolic and Localization genes is higher in normal queens and JH-treated workers, whereas more Developmental genes are up-regulated in normal and in Control workers.

Fenotypová plasticita a exprese genů

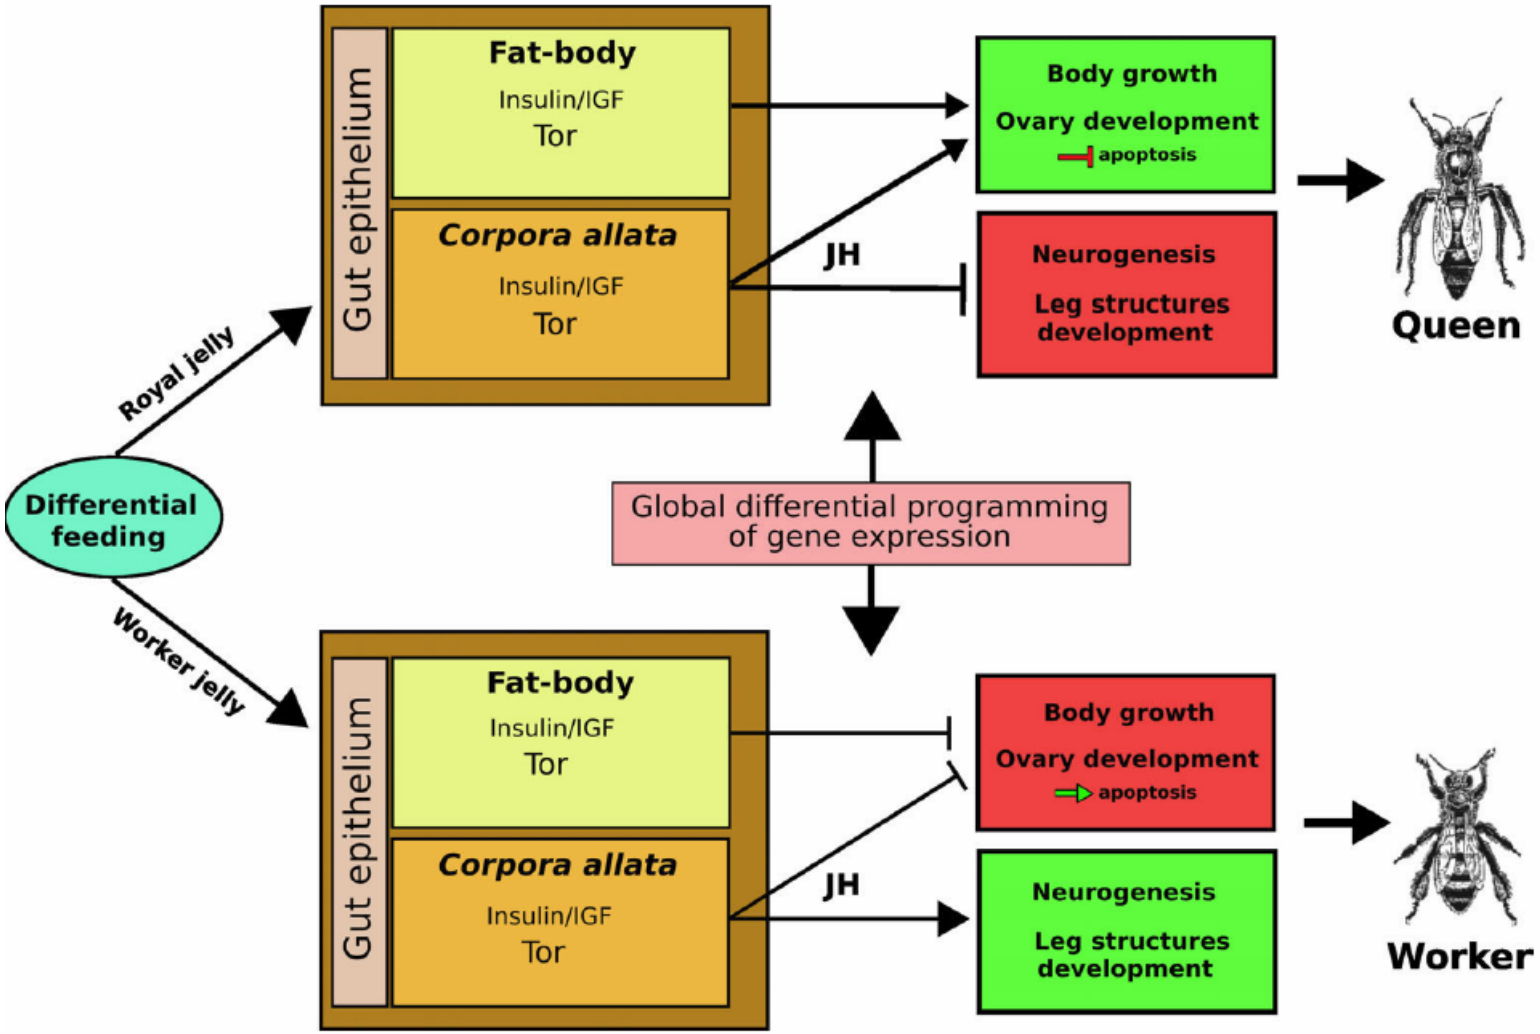

Figure 4
Proposed general model of caste differentiation in *Apis mellifera*. Arrows thickness indicates the relative action levels of the considered factors. Recent studies by our group suggest that the global differential programming of gene expression in the honeybee is controlled by DNA methylation mechanism in a manner similar to epigenetic transcriptional changes inducible by environmental factors in vertebrates (Maleszka et al., in preparation). For details see Section "Towards a unified model of caste differentiation in the honeybee".

Fenotypová plasticita a exprese genů

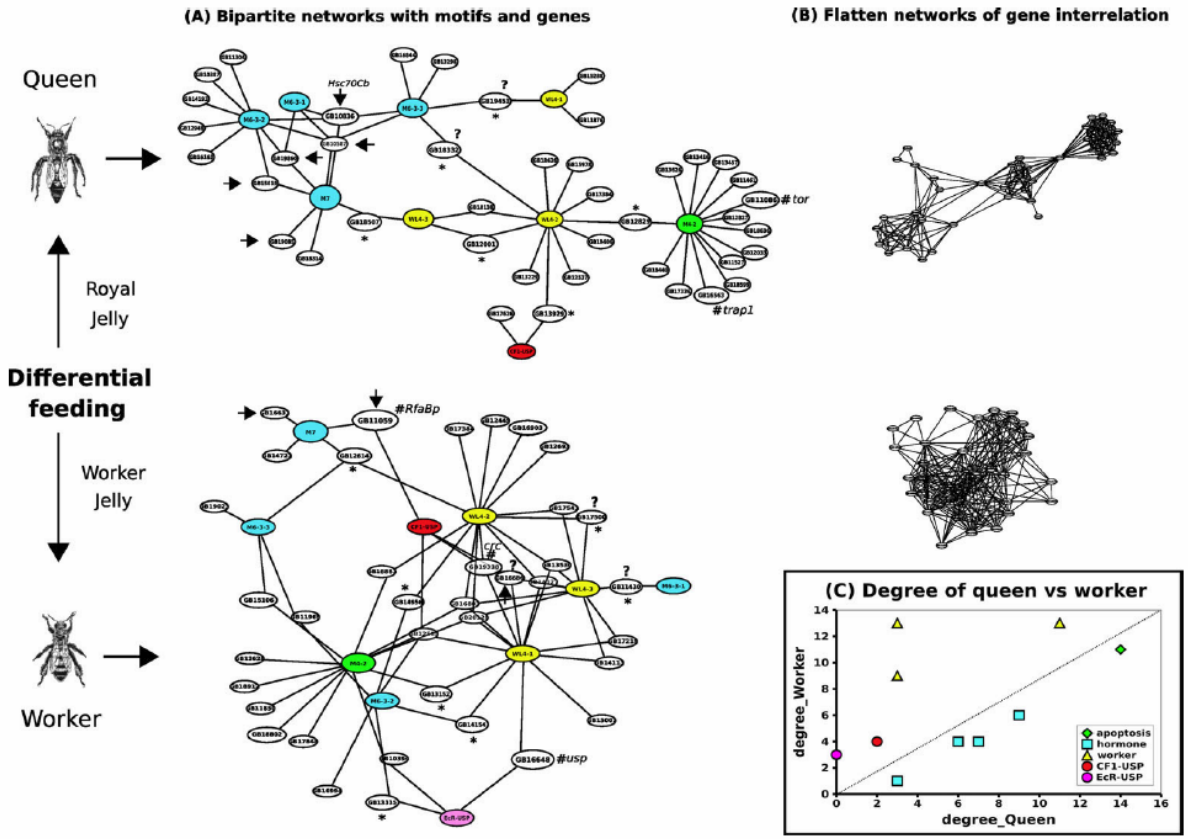

Figure 3
Networks depicting putative gene interactions based on the occurrence of overrepresented motifs in the UCR of DEG between *A. mellifera* castes. (A) Bipartite graph representing the occurrence of motifs (colorized circles) in the UCR of DEG in queen and worker castes. Motifs represented in blue were found in the functional group "JH responsive" (M6-3-1, M6-3-2, M6-3-3) and "hormone+caste" (M7), those in green were found in the functional group "apoptosis/other proteins" (M4-2), in yellow in top10-WL4 genes (WL4-1, WL4-2, WL4-3) and in magenta are motifs found experimentally in other insects (CF1-USP and EcR-USP). The black arrows point to genes coherently up-regulated in caste stages and JH assay. Genes with unknown function are marked by a question mark (?). Genes marked by an asterisk (*) were not in the training dataset for motif discovery. The worker DEG marked by a hash (#) are *usp, crc* and *RfaBp*, repressed by hormones. The queen DEGs marked by a hash (#) are *tor* and *trap1*, negative regulators of cell death in response to nutritional availability. (B) One layer graph (subsumed) designed to obtain measures of complex networks. Clustering coefficient (cc) and degree (d) show that worker's network (d = 62.21 ± 28; cc = 0.37 ± 0.23) is more interconnected than queen's network (d = 31.23 ± 15.67; cc = 0.36 ± 0.25). This suggests the worker DEGs share much more conserved *cis*-elements when compared to queen DEGs. (C) A plot obtained by representing each motif by a point with abscissa equal to its degree in the queen network and the ordinate equal to its degree in the case of the worker network. The fact that most nodes resulted above the main diagonal line (represented by the dashed line) objectively indicates that most promoters, except for "hormone" and "apoptosis" motifs, regulate more genes in the latter case (workers).

RNA interference

Mechanisms of gene silencing by double-stranded RNA

Gunter Meister & Thomas Tuschl

NATURE | VOL 431 | 16 SEPTEMBER 2004

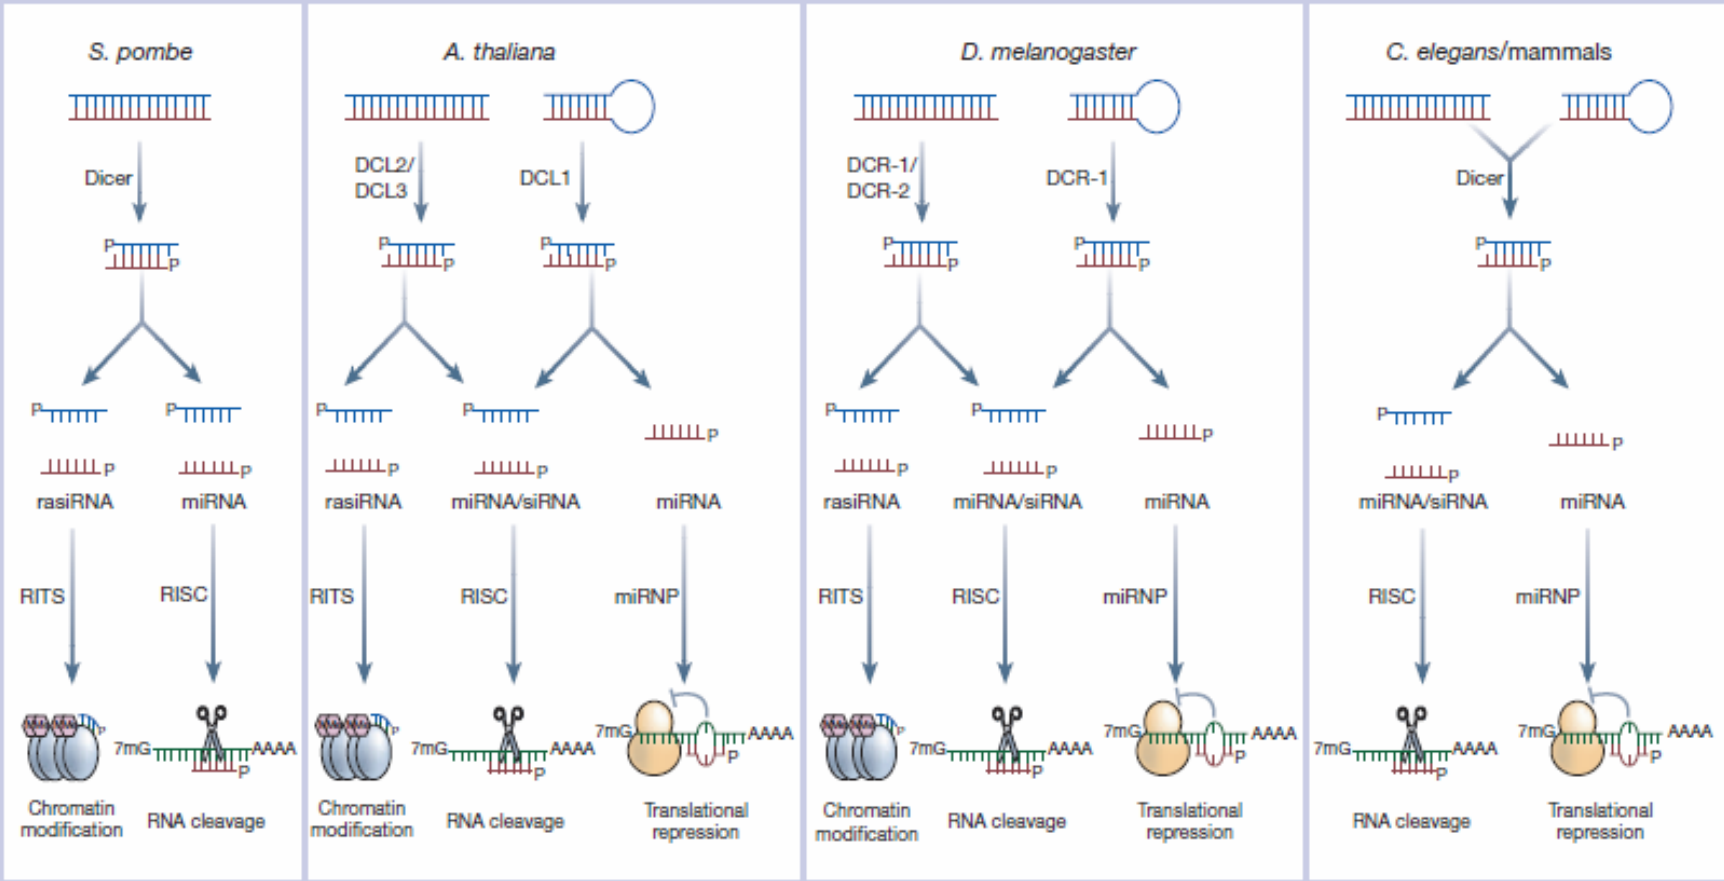

Figure 1 RNA silencing pathways in different organisms. Long dsRNA and miRNA precursors are processed to siRNA/miRNA duplexes by the RNase-III-like enzyme Dicer. The short dsRNAs are subsequently unwound and assembled into effector complexes: RISC, RITS (RNA-induced transcriptional silencing) or miRNP. RISC mediates mRNA-target degradation, miRNPs guide translational repression of target mRNAs, and the RITS complex guides the condensation of heterochromatin. In animals, siRNAs guide cleavage of complementary target RNAs, whereas miRNAs mediate translational repression of mRNA targets. rasiRNAs guide chromatin modification. *S. pombe*, *C. elegans* and mammals carry only one Dicer gene. In *D. melanogaster* and *A. thaliana*, specialized Dicer or DLC proteins preferentially process long dsRNA or miRNA precursors. 7mG, 7-methyl guanine; AAAA, poly-adenosine tail; Me, methyl group; P, 5′ phosphate.

Nutritional Control of Reproductive Status in Honeybees via DNA Methylation

R. Kucharski,* J. Maleszka,* S. Foret, R. Maleszka†

SCIENCE VOL 319 28 MARCH 2008

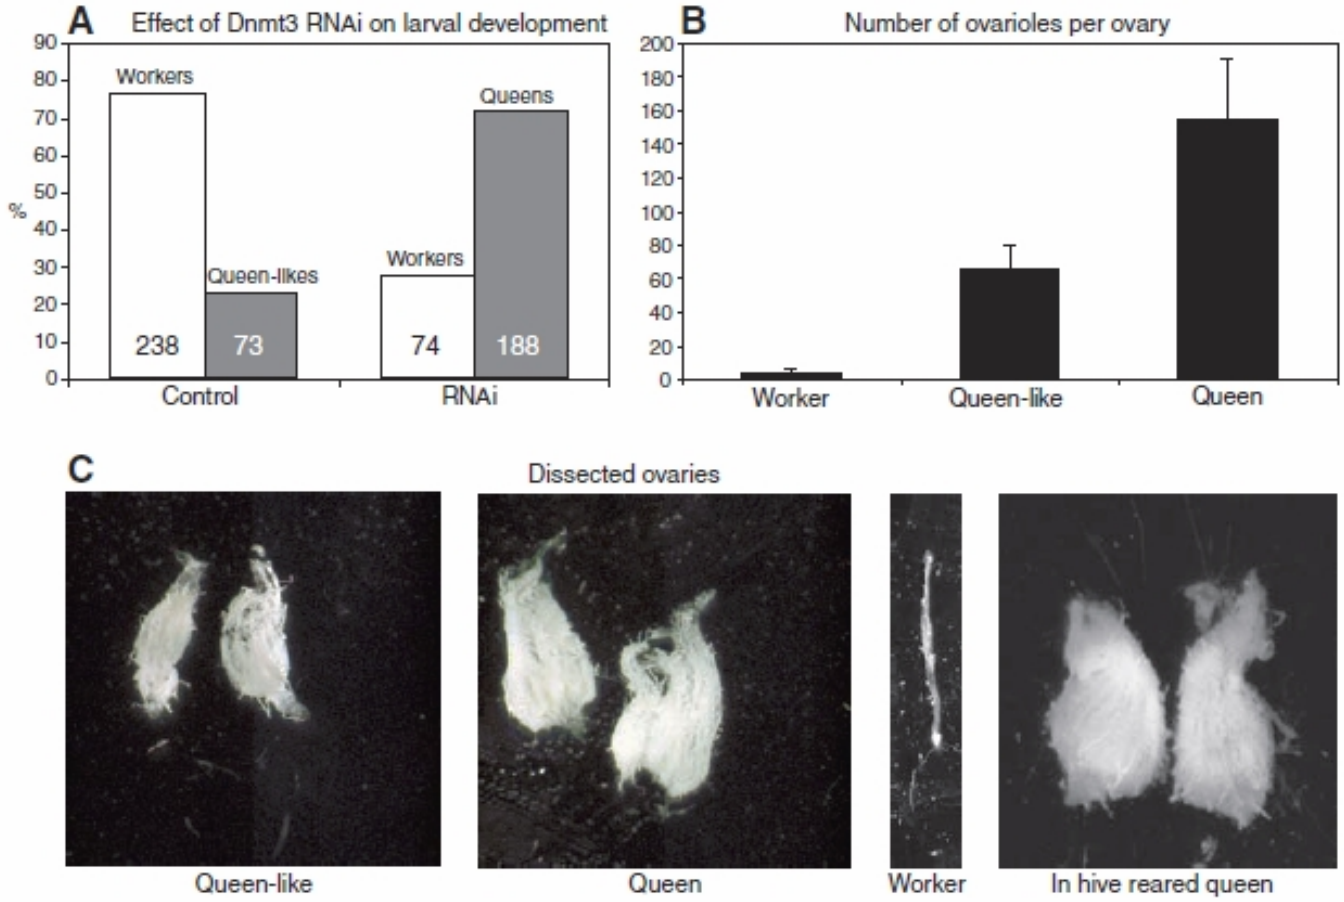

Fig. 2. Effect of Dnmt3 silencing on caste development in honeybees. Newly emerged larvae were injected either with a nonlarval control gene, *uth*, siRNA or with *Dnmt3* siRNA and allowed to develop until adulthood in a climate-controlled incubator. In both groups, the larvae developed normally, but the emerging adults displayed contrasting phenotypes. (**A**) The number of adults in each phenotypic category (workers, queens, and queenlikes). (**B**) The number of ovarioles per single ovary in each phenotypic class. Range error bars encompass the lowest and highest values. (**C**) Examples of ovaries dissected from each category and, for comparison, from a virgin queen reared in the hive on royal jelly. Queenlikes have queen morphological features but fewer ovarioles per ovary than queens [see (B)]. Workers have only rudimentary ovaries with two to six ovarioles. The figure is a compilation of four independent experiments. See (*21*), table S2, and fig. S1 for more details and results from individual experiments.

Exprese genů souvisí s epigenetickou modifikací DNA

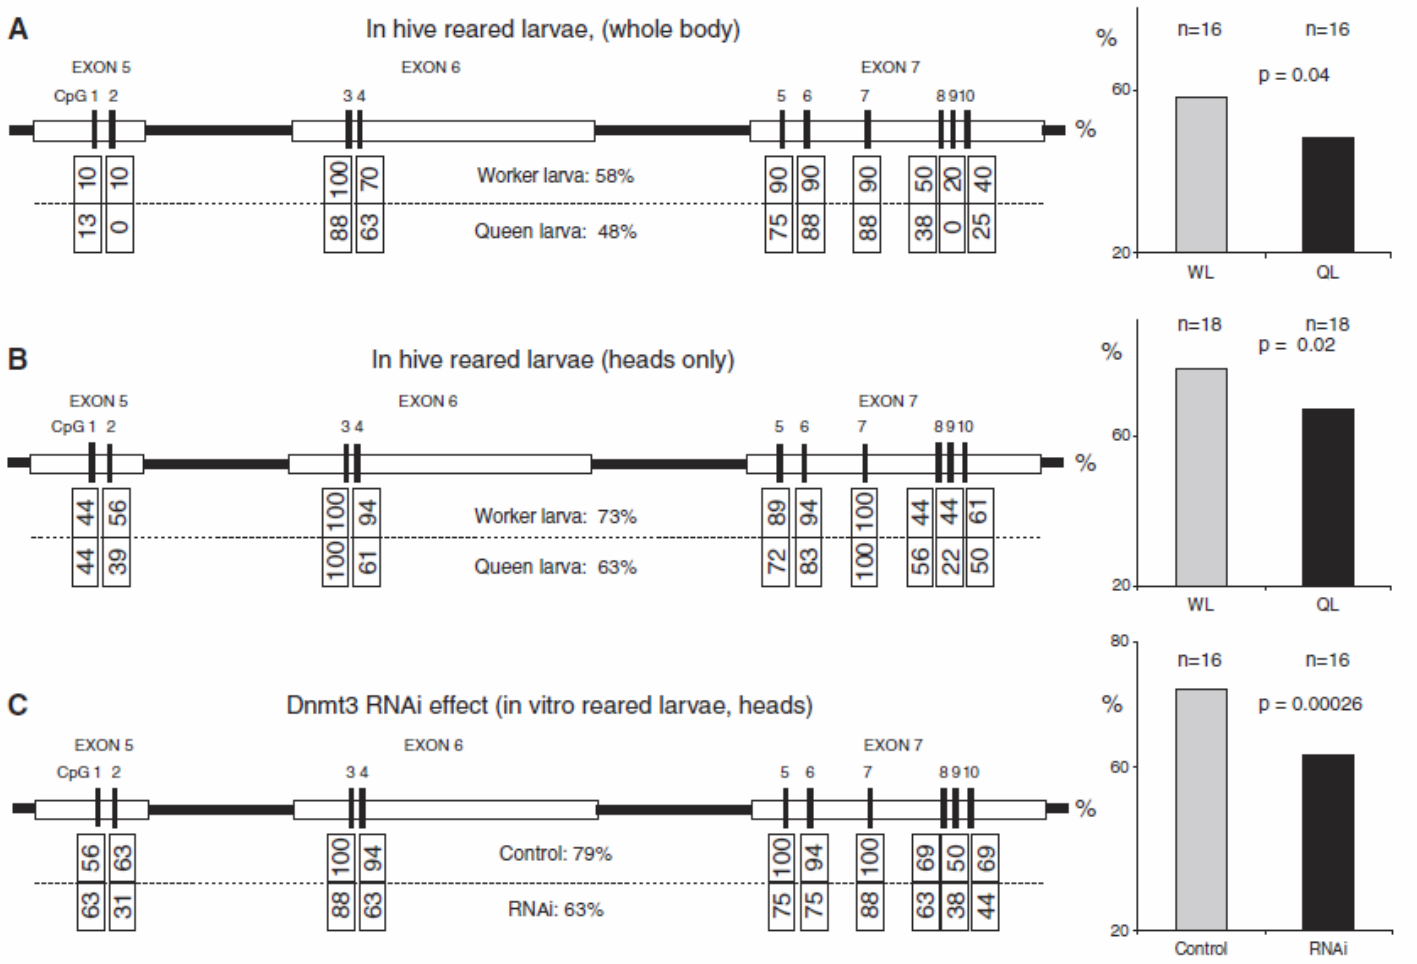

Fig. 3. Methylation status of cytosines in CpG dinucleotides of *dynactin p62*. The percentage of methylation for individual CpGs is shown in boxes, and the overall methylation in the right-hand graphs. DNA was isolated by using larvae collected (**A** and **B**) from the hive [for (A), pooled whole late-L3 larvae, $n = 7$; for (B), heads only, $n = 20$ for workers and $n = 14$ for queen larvae] and (**C**) from pooled heads of late-L3 in vitro reared larvae ($n = 7$). The number of clones sequenced for each category is shown above the bars in the right-hand graphs. Methylation quantities along this gene were analyzed with a general linear model of the binomial family (*31*) by using treatment (diet or RNAi) and position as factors to model the state of each CpG. The differences between queen larvae (QL) and worker larvae (WL) as well as the effect of RNAi are statistically significant.

Shrnutí

- Fenotypová plasticita je často spojena se změnami metabolismu hormonů a alternací v expresi genů
- Změny exprese genů jsou často spojeny se změnami struktury chromatinu
- Fenotypová plasticita však může být spojená i s postranslačními procesy
