Opportunities and challenges of application of satellite remotely-sensed data in Land System Science

Alexander V. Prishchepov

alpr@ign.ku.dk

2nd EARSeL SIG LU/LC and NASA LCLUC joint Workshop “Advancing horizons for land cover services entering the big data era”, May6-7, 2016, Prague
Outline

- Data accessibility
- Quality of the products
- Matching community needs
Motivation for this talk

- Post-Doc 2010-2014 at IAMO
- 60 researchers with focus on agricultural economics and land system science
- Key research directions: structural development of farms and rural areas, agricultural markets, policies, theory of structural change
- Limited use of remote sensing products across IAMO

http://www.iamo.de/lsc
Emerging field of Land System Science

Human interactions with the natural environment

Necessity:

• to monitor land use dynamics and its intensity
• Understand the drivers
• Predict the change
• Assess feedback to the Earth System

Critical role of satellite remote sensing is emphasized!

Verburg et al. 2015, Anthropocene
Living in exciting time!

Shift of the paradigm of agencies’ behavior regarding data accessibility (freeing Landsat archives, LDCM & Sentinel-2 programs)

Monthly summary of scene downloads from the EROS Data Center

However..

- 39 satellites carry optical sensors that allow to record satellite images with finer than 100m spatial resolution

- However, only two programs so far allows free access for satellite images archive

......*there is room for improvement*

However...

- Preprocessing and classification of datasets requires computational facilities (big data)
- And skilled personal
- Not so many institutions can afford
Screening over 2,000 publications (2011-2015) in Remote Sensing of Environment showed only in few publications authors considered to place datasets as Supplementary or provide a link for data download.
Son, it was a great time, so many publications, exotic field trips, and awards. Access to publications by subscription and my ignorance of opening collected data gives you a chance to write a thesis about their backwardness.
What can we do about that

- Elsevier-like journals offer opportunity to upload datasets, appendix, supplementary
- Universities require and have facilities to store datasets, including freezing data options (i.e. UCPH M. Penkowa case)
- Funding agencies? Requirement to release the products after 3 year period following the official end of the project

- Increase the awareness about existing LULCC products!
- Interdisciplinary workshops,
- Brown bag seminars,
- Special calls and issues of the journals
Increasing role of the commercial players

Quality of LULCC products

• It is often believed remote sensing provides reliable and unbiased information about LULCC
• Products are used without account for induced errors
• What is the cut-off to decide, whether RS product is useful or not for LU models?

Potential false land cover change due to difference in quality of land cover products

Results

• For “abandoned arable land” only three predictors were statistically significant for the best overall classified map (#49) (“distance from nearest forest edge”, “distance from nearest road”, “distance from nearest village”) 9 times out of 10 models.

• With decrease of image-dates models became unstable, particularly, with “one-and-one” image dates combinations

• Suggested cut-off to use classifications, at least of 80% of UA, PA and individual class Kappa for classes of interest
Solutions

Boosting accuracies of classifications:

• Image fusion (Landsat archives+Sentinel-2, MODIS, other sensors)
• Emerging role of SAR imagery and LiDAR
• Ancillary data (DEM, texture, phenology metrics)
• Better understanding the sensitivity of LULCC models to error-induced LULCC maps (studying error propagation and uncertainties related to produced LULCC products is essential)
### Summary and test results of input data enhancement categories

Agricultural economics perspective

- Structural characteristics of farms (size of farms, productivity, profits and losses, efficiency of production)
- Land use intensity (how often fields are cultivated, inputs, timing of sowing, harvesting, utilization of irrigated areas)
- Different crop types rather cropland vs. other classes
- Grazing intensity, grassland productivity
- Bioenergy production vs. traditional crops
- There is strong need in wall-to-wall systematic observations of above mentioned parameters, while case-studies also bring incredible asset!

**ABSTRACT**

Index insurance is becoming increasingly popular because of its ability to provide low-cost, relatively easy to implement agricultural insurance for vegetation types whose productivity has been notoriously difficult to measure and to farmers in less-developed nations where traditional crop insurance schemes are not reasonable to implement. This study examines if the remotely sensed normalized difference vegetation index (NDVI) can be an effective basis for index-based crop insurance over a diverse set of locations. To do this the authors compare Advanced Very High Resolution Radiometer (AVHRR) values to cumulative precipitation, extreme heat, and crop yields for 60 locations across the United States for the years 1982-2003. Quadratic regression equations are used to explore these relationships. The findings suggest that the relationship between NDVI, precipitation, extreme heat, and crop yields is highly variable and dependent on location-specific characteristics. Without site-specific calibration, NDVI should not be widely applied to index-based insurance product design. However, NDVI may still be a useful tool in insurance design under certain circumstances. This may be disappointing to proponents of NDVI as a risk transfer mechanism but the authors believe it important to report negative results as a caveat, and to give researchers and practitioners pause before investing time and money into the proposition.
Detailed track of timing of LULCC is critical

Mapping conversion of forest to rangeland in Amazon with Landsat imagery

- Carbon balance
- Assessing spillover effects
- “Blaming” the victims

Source: Verburg et al. 2015, Anthropocene
Carbon uptake substantially increases after 10 years of abandonment

Cropland abandonment resulted in a net carbon sink of 470 TgC for 1990 to 2009

Only in Russia alone one third of CO2 industry and fossil fuels emissions are offset by abandonment

Schierhorn et al. 2013, Global Biogeochemical Cycles
What can we do about that?

- Systematic mapping of land-use intensity
- Development of the new techniques (i.e., time-series analysis of Landsat-like archives, data fusion)
- Freeing the archives and the datasets
- Targeting the societal needs via collaboration with potential end-users
- Making the products understandable and user-friendly for broad-scale audience
Thank You!
