Specialist invertebrates

4 April 2009 – 54cm

27 July 2009 – 128cm

Existing research

- **Sadler & Bates 2008**
ERS is utilised by a large number of high affinity species, often with high levels of rarity.
- **Paetzold et al 2005**
On a large, braided river (Tagliamento), aquatic prey accounted for > 80% of prey items.
- **Hering et al 2004**
Local population recovery following major flood events is species specific.
- **Greenwood et al 2010**
Low flows suppress specialist abundances.

Paetzold et al 2005

How does this disturbed, nutrient poor resource support so many specialist species at relatively high abundances?

Hypotheses

- Strategies to avoid/survive inundation pressures will cause species-specific variations in prey selection.
- Variations in inundation risk at patch scale will cause within-species switches to alternative food sources.

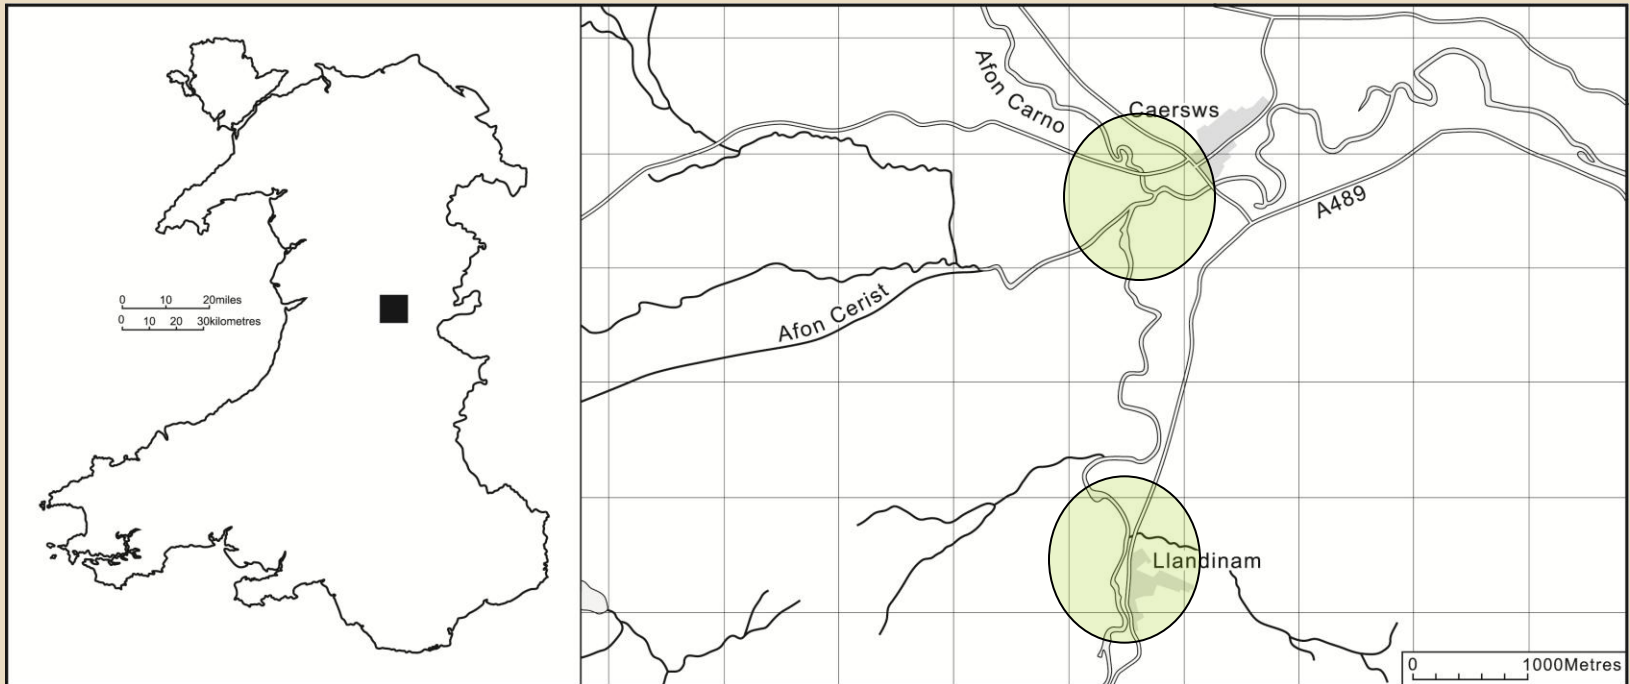

Stable Isotopes to indicate nutrient sources

- Naturally occurring heavier isotopic forms ($\delta^{13}\text{C}$ and $\delta^{15}\text{N}$) can be used to trace nutrient pathways (proportions vary spatially, temporally and between ecosystems).
- Lighter, more abundant forms preferentially metabolised and excreted, consumers are more enriched than prey
- Enrichment occurs at a predictable level, the Trophic Enrichment Factor (TEF)
- Arthropods: $\delta^{15}\text{N} = 2.3 \pm 0.16 \text{ ‰}$
 $\delta^{13}\text{C} = 0.5 \pm 0.13 \text{ ‰}$

Combining morphology, GLM and correlations

	Summary	Species
Group1	Specialist ground beetles, headwater	<i>Bembidion atrocaeruleum</i> , <i>Bembidion decorum</i>
Group 2	Specialist ground beetles, floodplain	<i>Bembidion punctulatum</i>
Group 3	Low affinity ground beetles	<i>Bembidion tetracolum</i> <i>Paranchus albipes</i>
Group 4	In-land ground beetles	All other species
Group 5	Specialist non-ground beetles	<i>Stenus</i> sp <i>Coccinella 5-punctata</i>

Isotope data: Consumers & prey

n = 398

	$\delta^{13}\text{C}$	St Dev	$\delta^{15}\text{N}$	St Dev
Group 1	-26.03	1.34	10.93	1.35
Group 2	-25.60	1.31	11.43	1.35
Group 3	-26.23	1.07	9.95	1.36
Group 4	-26.59	1.09	8.20	2.00
Group 5	-26.47	1.45	7.89	1.88

Isotopic niche

How does inundation risk impact prey selection?

Headwater species

B. atrocaeruleum

Low risk

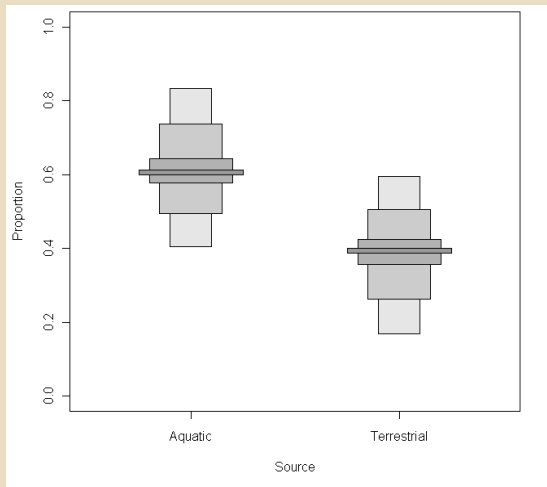

Medium risk

High risk

Floodplain species

B. punctulatum

Low risk

Medium risk

High risk

Low affinity species

B. tetracolum

Low risk

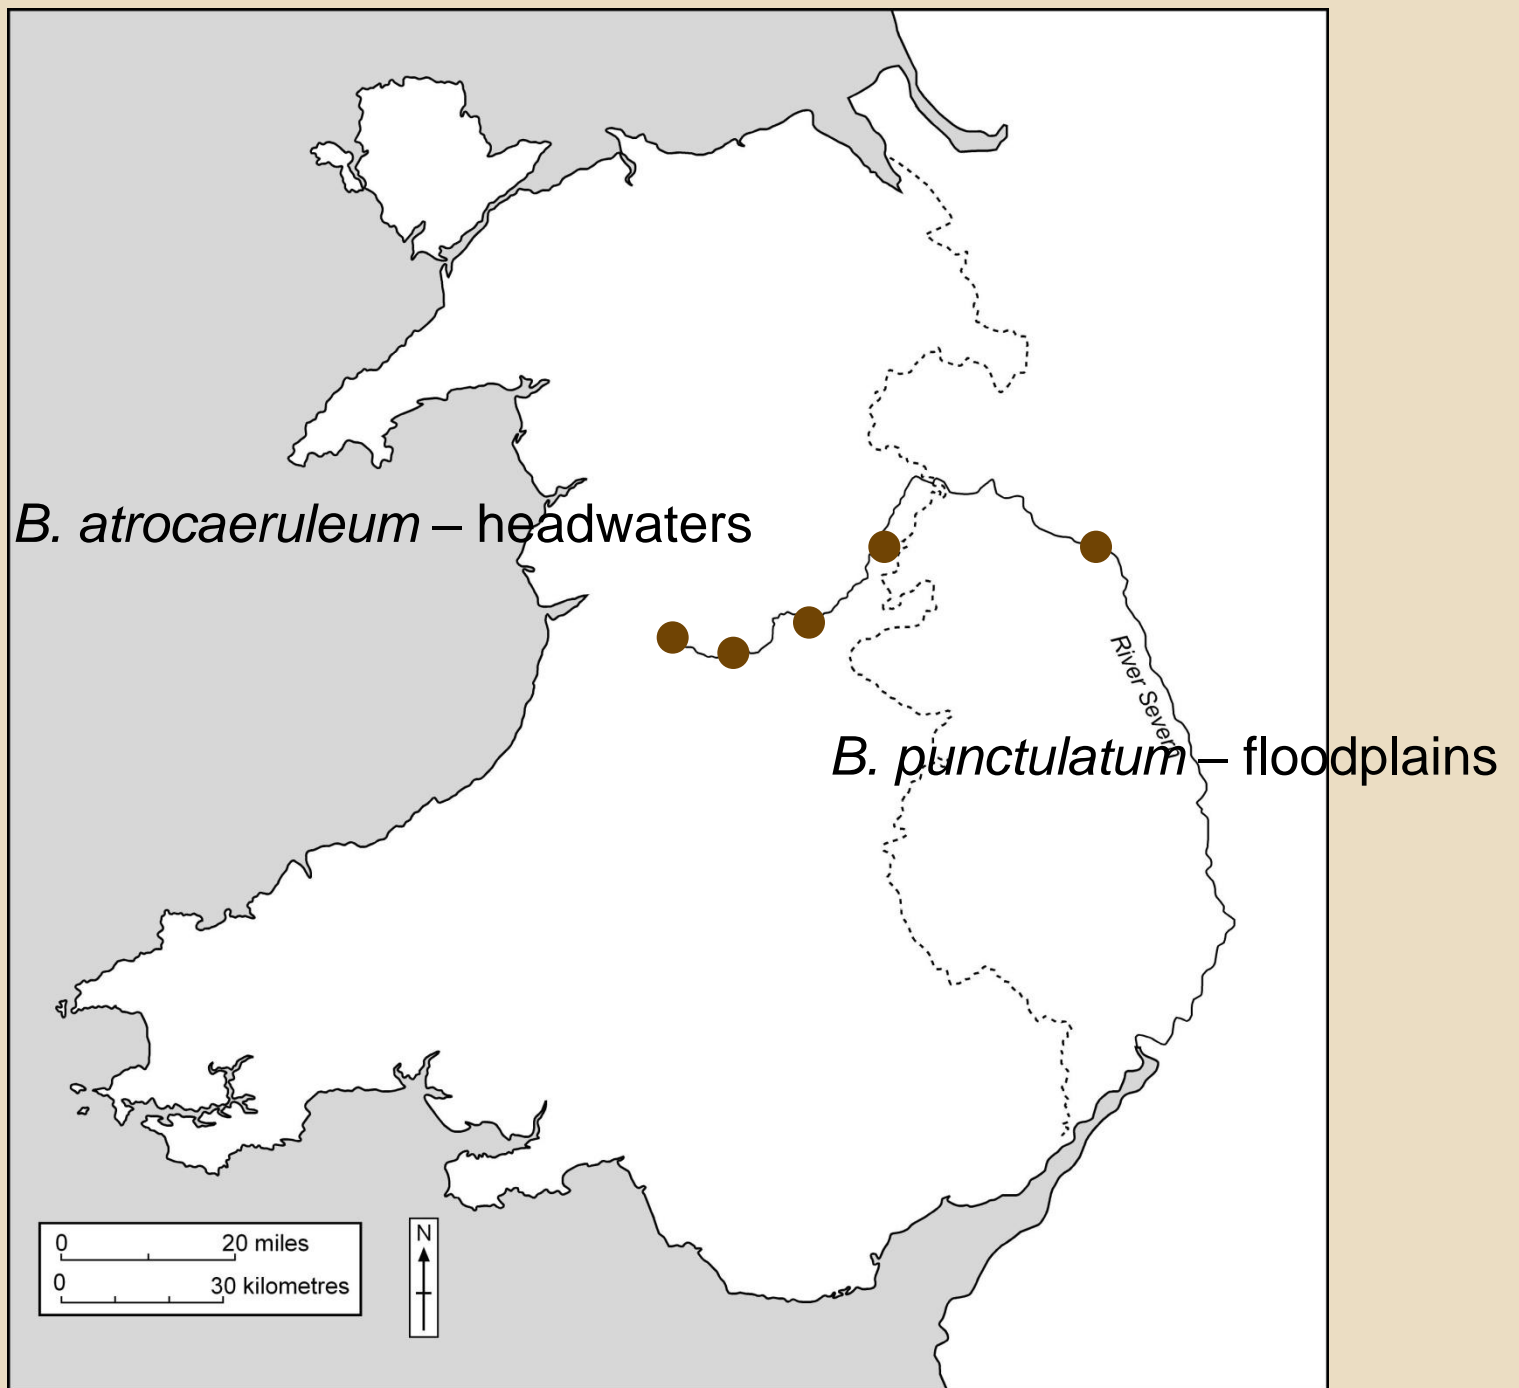

Medium risk

High risk

- Specialist ground beetles show variations in local positioning and regional abundances.
- They also show variations in dietary composition according to inundation pressure
- Are these variations an indication of different functions? i.e. is prey selection and positioning inherent?

B. atrocaeruleum

Conclusions

- Specialist ERS ground beetles are highly adapted to the demands of their optimum habitat, such that inundation has minor impact on feeding strategies.
- Small differences in adaptations alter assemblage structure at a regional scale and the level of aquatic nutrient uptake.
- Less well adapted ground beetles exhibit a strong aversion to flooding risk.
- Non-ground beetle specialists have a dependency on the habitat, but not aquatic subsidy. They are also poorly morphological adapted.
- The resource contains multiple niches – overlapping and requiring differing specialisations that define the optimum habitat.
