# Local physical habitat quality cloud the effect of predicted pesticide runoff from agricultural land in Danish streams

Jes J Rasmussen Annette Baattrup-Pedersen Brian Kronvang

### Outline

- > Transport routes for pesticides to streams
- > Introduction to the SPEcies At Risk (SPEAR) concept
- Predicted pesticide runoff in Danish streams and its impact on stream macroinvertebrates
- > The role of the physical properties
- > Confounding factors

#### I. Major transport routes for pesticides

## Frequency is similar while max. concentration is significantly higher in small streams

|               | Large streams |               | Small streams |               |
|---------------|---------------|---------------|---------------|---------------|
|               | Frequency     | Concentration | Frequency     | Concentration |
|               | (%)           | Max (µg/l)    | (%)           | Max (µg/l)    |
| Isoproturon   | 41            | 0.13          | 48            | 2.1           |
| Diuron        | 37            | 0.073         | 29            | 0.36          |
| Bentazon      | 25            | 0.028         | 37            | 1.2           |
| Fenpropimorph | 0             | 0             | 3             | 0.11          |
| Dimethoat     | 2             | 0.034         | 4             | 0.12          |

Examples of frequency and maximum concentrations of pesticides in two stream types from the Danish Monitoring Program (NOVANA)

Jes J Rasmussen H

HydroEco May, 2011

#### II. SPEAR concept

Modified after Liess et al., 2008

#### III. Predicted pesticide runoff in DK streams

212 sites sampled yearly in 2004-2007

The RP model considers

- > Precipitation events
- > Soil characteristics
- > Crop types and growth phases
- > Agricultural intensity
- > Field slopes
- Applied amounts for a generic compound was set to constant (limited data)

#### Impact of predicted pesticide runoff

%SPEAR abundance represents the arithmetric mean of 4 yearly samples from 2004-2007

#### IV. The role of physical properties

| Parameter                                    | DCA 1   | DCA 2   |  |  |
|--|---------|---------|--|--|
| Silt (%)                                     | 0.35*** | -       |  |  |
| Gravel (%)                                   | 0.40*** | -       |  |  |
| Agricultural intensity                       | 0.11*   | -       |  |  |
| Upstream riparian habitat quality            | 0.31*** | -       |  |  |
| Catchment size                               | -       | 0.43*** |  |  |
| Substrate heterogeneity                      | -       | 0.22*** |  |  |
| Pearson correlation with DCA ordination axes |         |         |  |  |

#### V. Confounding factors

NATIONAL ENVIRONMENTAL RESEARCH

INSTITUTE

AARHUS UNIVERSITY

 Applied amounts of pesticides increase with decreasing latitude – but is not picked up by RP

Schriever et al., 2007b

NATIONAL ENVIRONMENTAL RESEARCH INSTITUTE AARHUS UNIVERSITY

#### Jes J Rasmussen H

HydroEco May, 2011

#### **Buffer strips**

- Measures of buffer strip
  retaining capacity are not
  included in the RP model
- Buffer strips are known to retain significant proportions of pesticide runoff

![](_page_9_Figure_6.jpeg)

Field based data from 2009 in 15 Danish low-order streams. Pesticides sampled with event triggered samplers.

#### NATIONAL ENVIRONMENTAL RESEARCH INSTITUTE AARHUS UNIVERSITY

### Conclusion

- Buffer strip characteristics improve predictive power of the RP model – and is tightly coupled to the occurrence and toxicity of agricultural pesticides in DK streams
- Despite the presence of buffer strips and relatively low pesticide application rates, the toxicity of found pesticide mixtures still exceed the threshold of expected community change
- However, poor physical stream properties can cloud these changes – at least in the absence of extreme events of pesticide contamination
