

Evolutionary genetics

2/1 Zk/Z

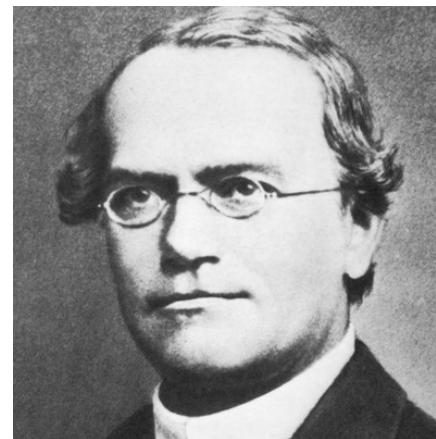

Radka Reifová

Evolutionary genetics

- Combines Darwin's evolutionary theory (1859) and Mendel's theory of inheritance (1866).
- Aims to understand the diversity of life from a genetic perspective, using DNA sequences to study population history and evolution.

Charles Darwin

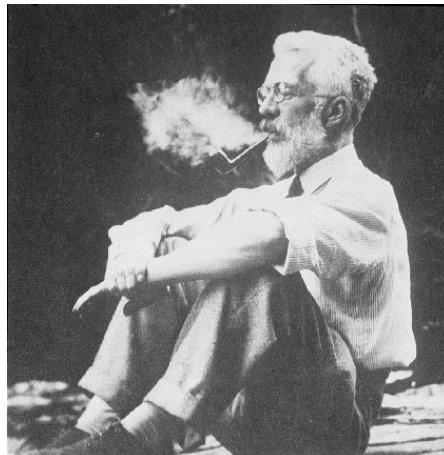

Johann Gregor Mendel

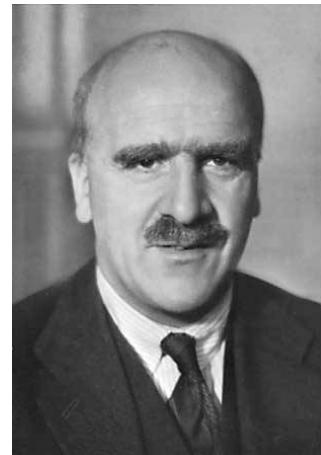

Milestones of evolutionary genetics

Modern synthesis (1930s–1940s)

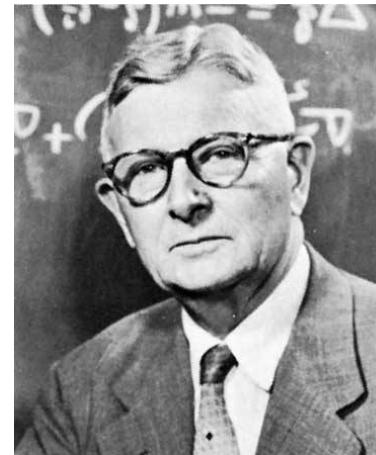

- synthesis between Mendelian genetics and Darwin's selection theory

Sir Ronald Fisher

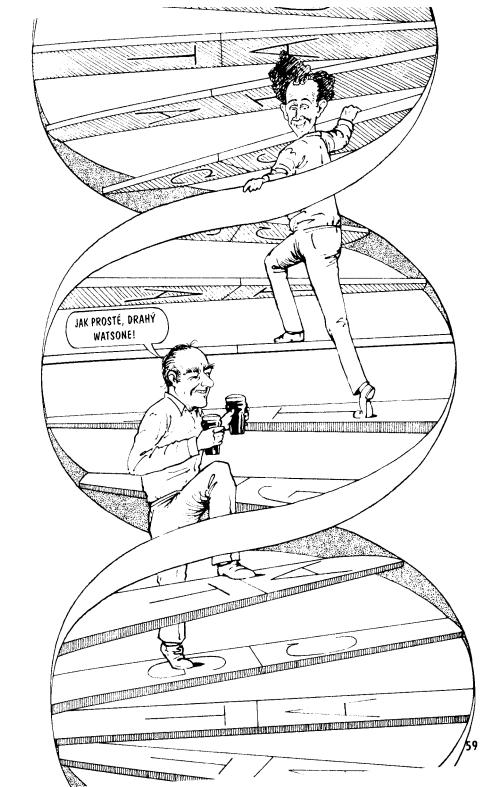

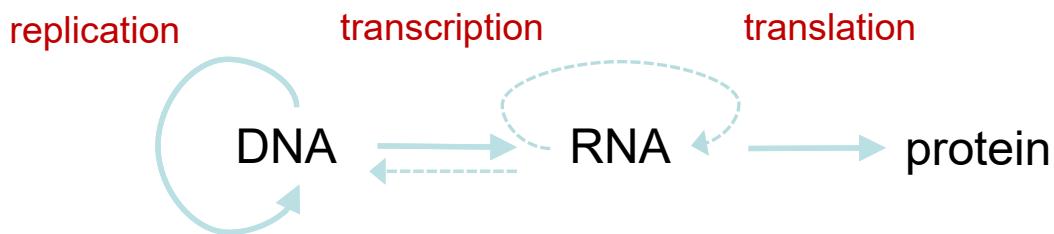

J. B. S. Haldane

Sewall Wright

Milestones of evolutionary genetics

Discovery of DNA structure (1953)
Central dogma of molecular biology (1950s)

James Watson a Francis Crick

Theory of molecular evolution
(1970s)

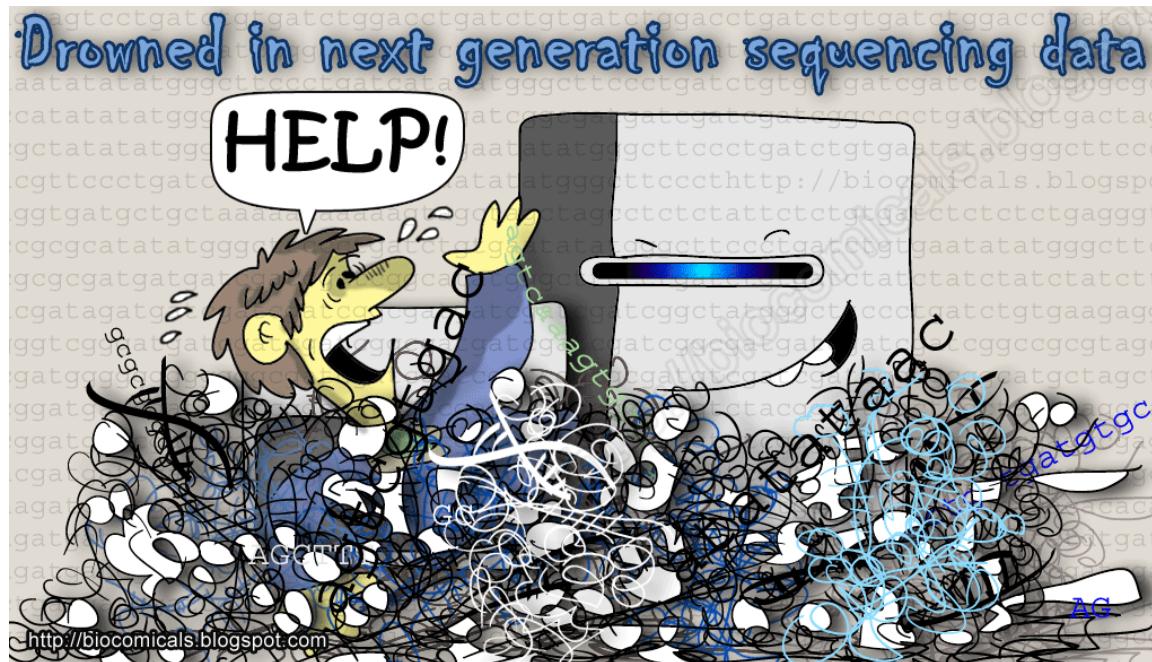

Motoo Kimura

Milestones of evolutionary genetics

Discovery and development of sequencing technologies (since 1970s)

- Sanger sequencing
- Next-generation sequencing methods

Genome sequences

- 1995 *Haemophilus influenzae*
 - 1996 *Saccharomyces cerevisiae*
 - 1998 *Caenorhabditis elegans*,
 - 2000 *Drosophila melanogaster*
 - 2001 *Homo sapiens*
 - 2002 *Mus musculus*
 - 2005 *Pan troglodytes*
 - 2010 *Homo neanderthalensis*

- 2012

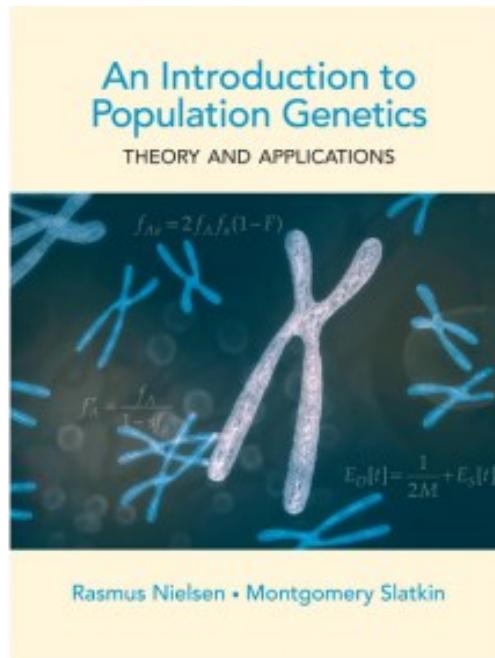

Schedule

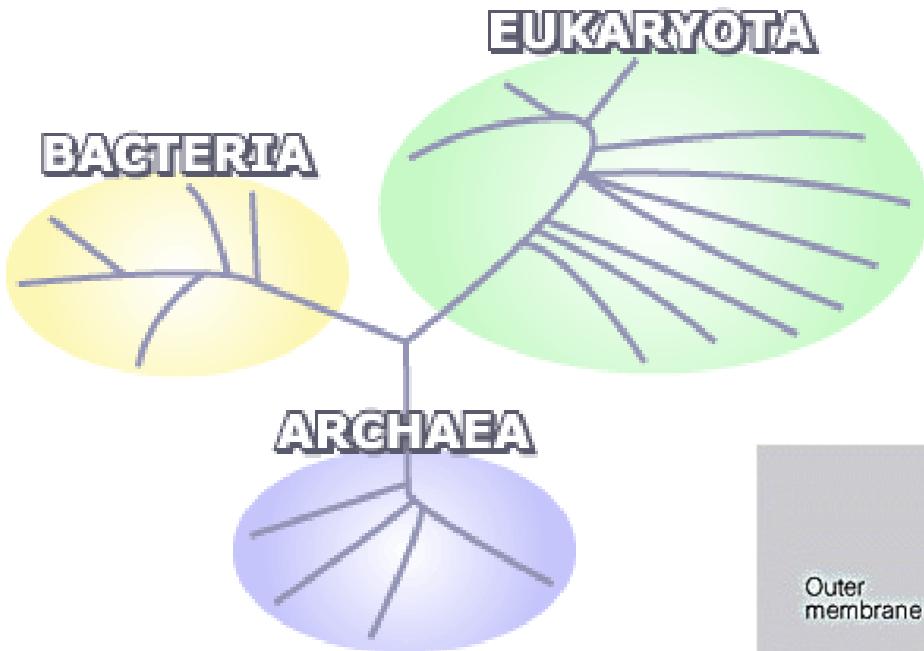

- 2.10. Genes and genomes
- 9.10. -
- 16.10. -
- 23.10. Inheritance
- 30.10. Students' presentations**
- 6.11. Introduction to population genetics
- 13.11. Neutral evolution, molecular clocks
- 20.11. Selection
- 27.11. Students' presentations**
- 4.12. Functional genetics
- 11.12. Speciation
- 18.12. Gene genealogies and phylogenies
- 8.1. Students' presentations**

Materials for the exam

- Presentations from lectures, student's presentations, recommended articles
- An Introduction to Population Genetics (2013)
Rasmus Nielsen and Montgomery Slatkin
- Other books about population and evolutionary genetics

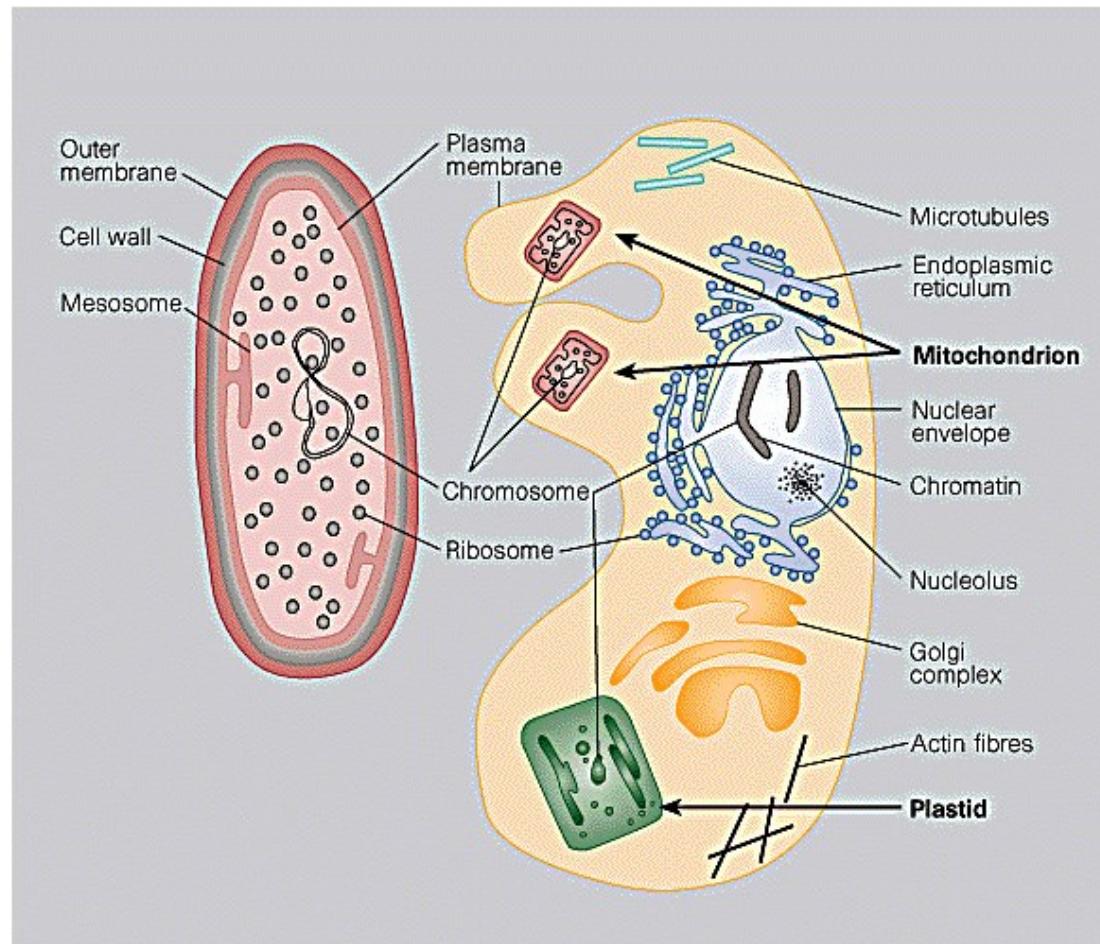

Genes a genomes

Genome size and C value paradox

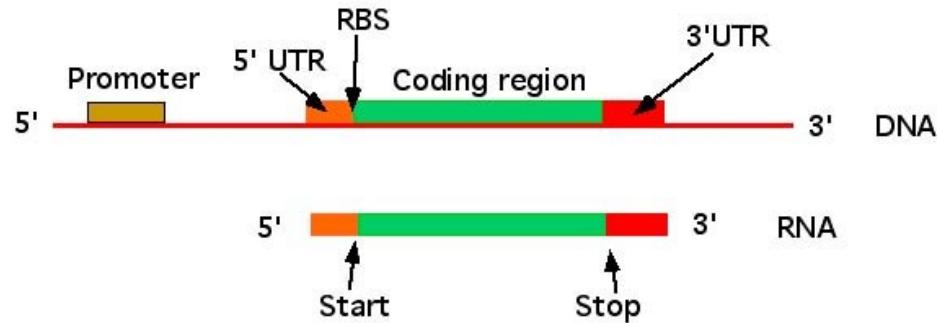

Genome size and C value paradox

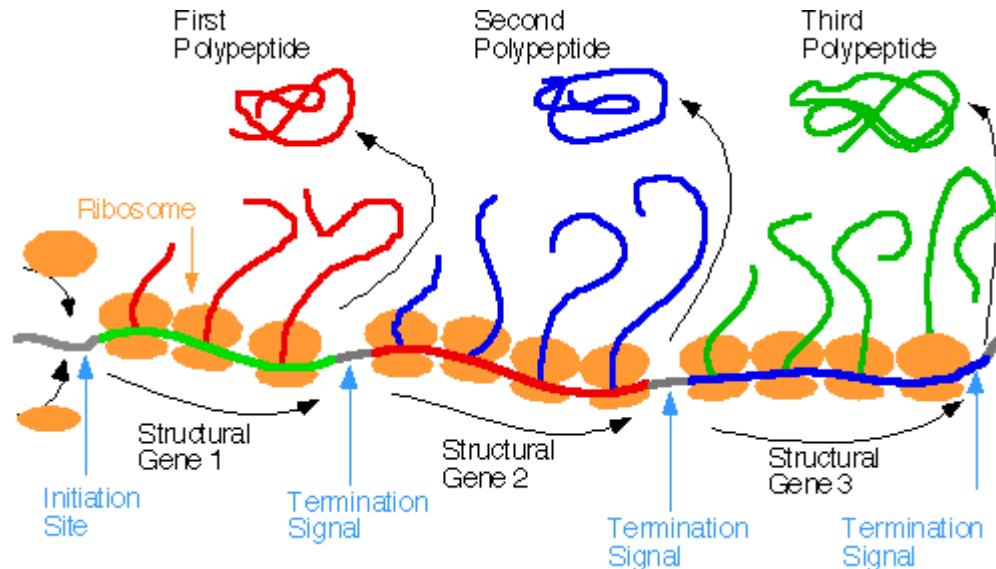

Protein coding genes – bacteria and archaea

- Simple genes (without introns).

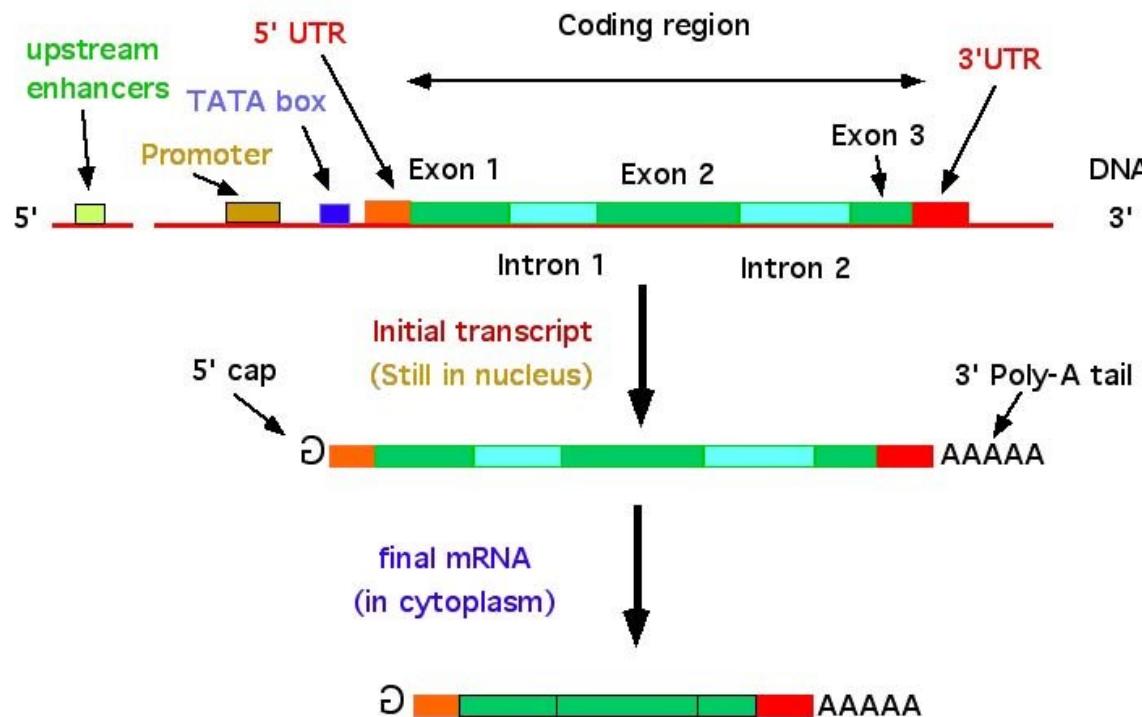

- Operons

Protein coding genes – eukaryotes

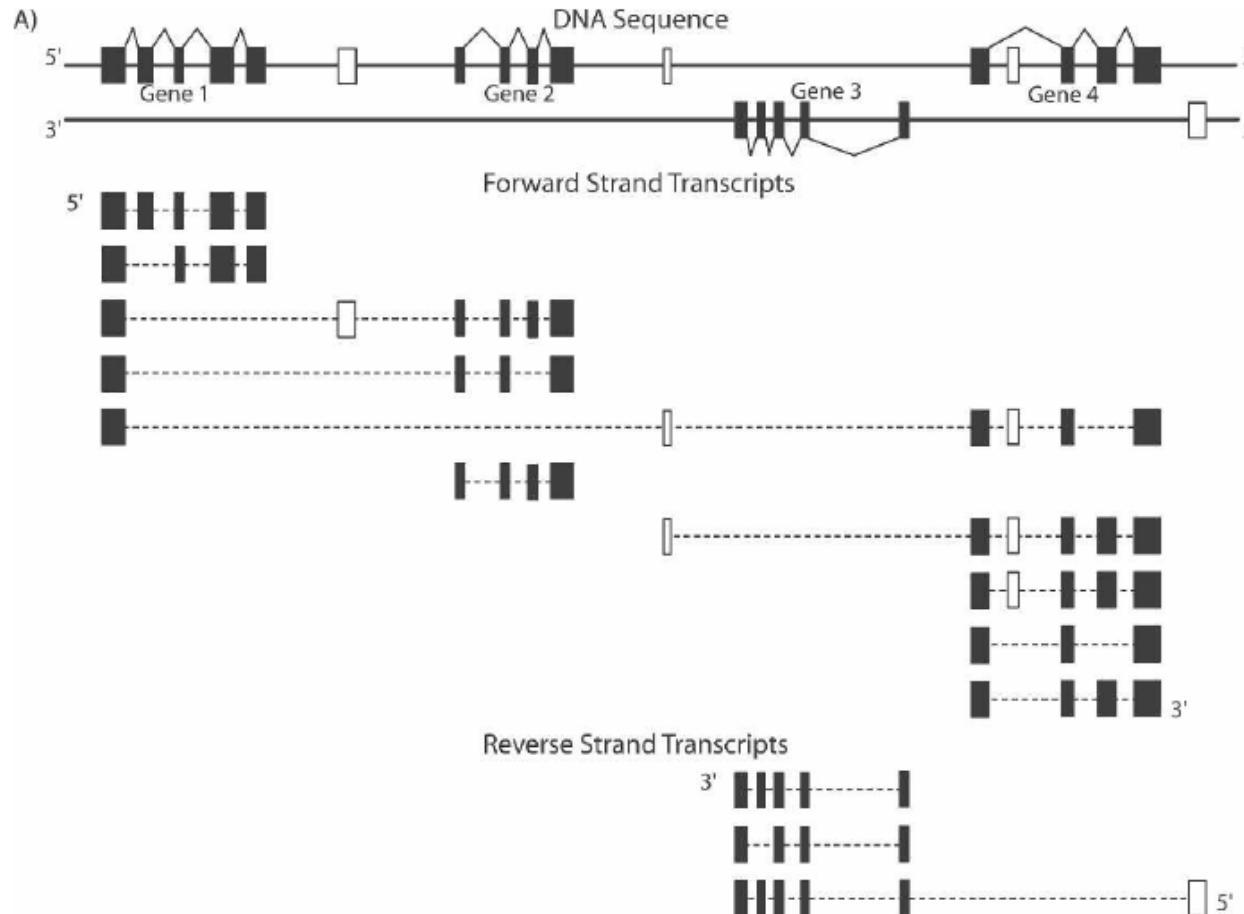

- Contains exons and introns
- Splicing by spliceosome
- Alternative splicing, more proteins from a single gene
- Regulatory regions (promoters, enhancers)

Alternative splicing

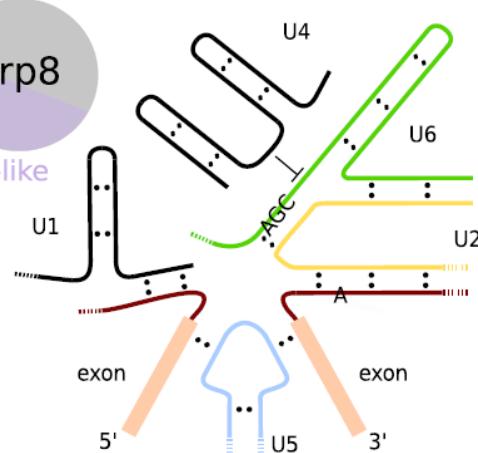

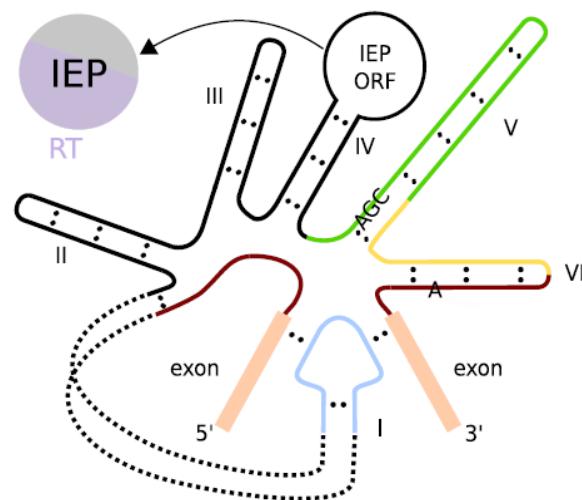

Alternative promoters and terminators of transcription

- On average 6.3 alternative transcripts per gene

Origin of spliceosome from bacterial selfsplicing introns

Intron encoded protein

Numbers of protein coding genes in genomes

Mycoplasma genitalium

470

Haemophilus influenzae

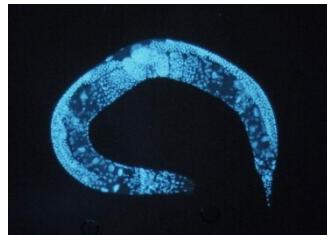

2 000

Saccharomyces cerevisiae

7 000

Caenorhabditis elegans

20 000

Drosophila melanogaster

14 000

Homo sapiens

21 000

Mus musculus

23 000

Danio rerio

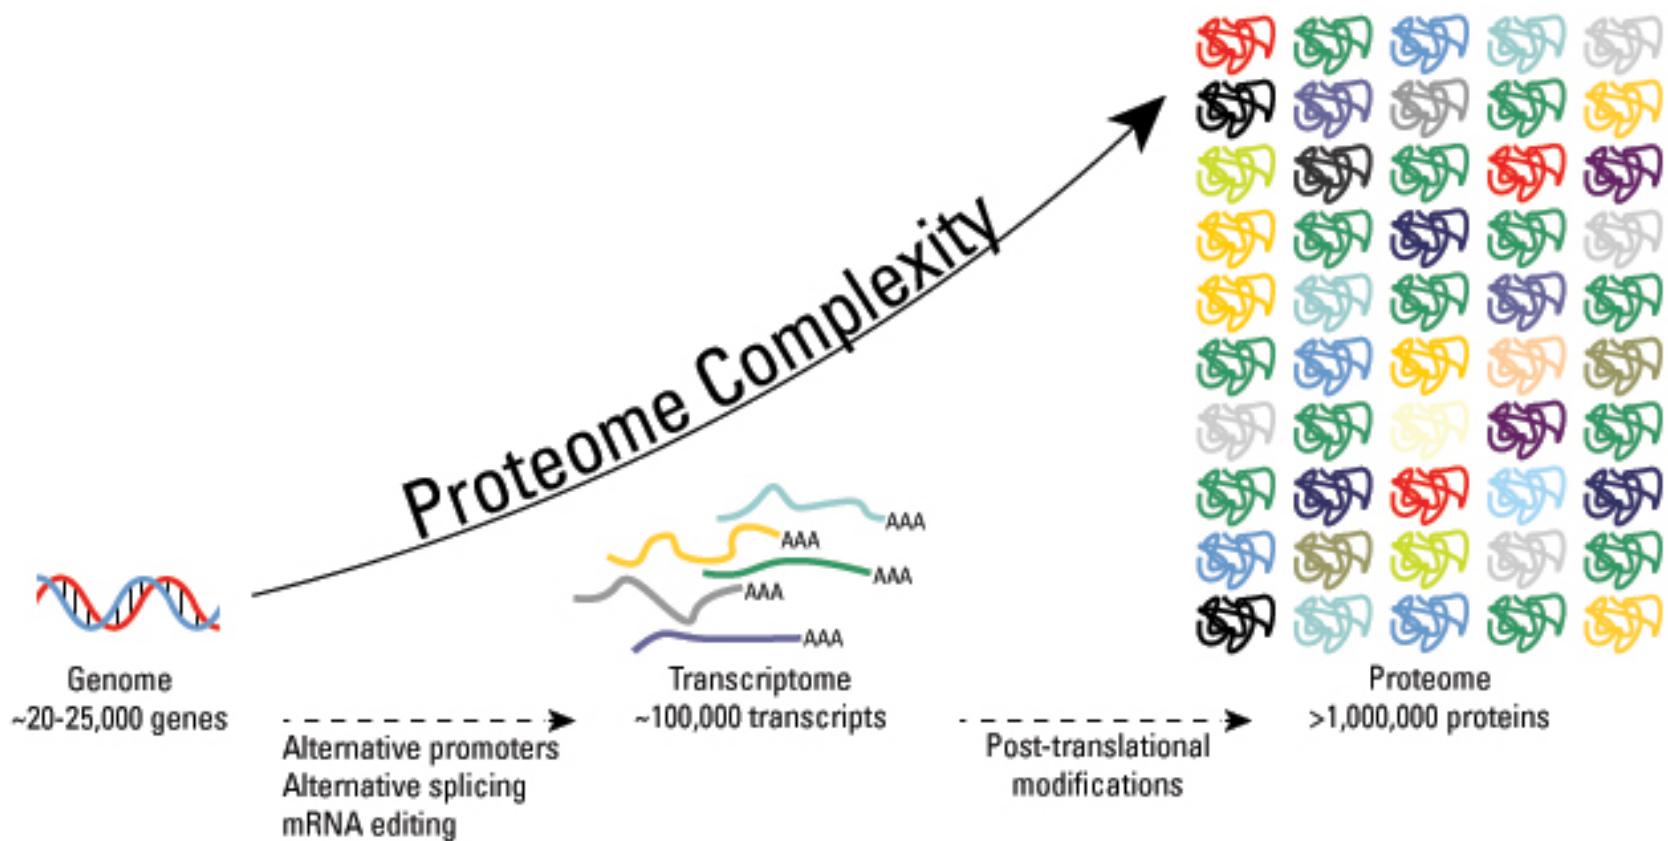

26 000

Arabidopsis thaliana

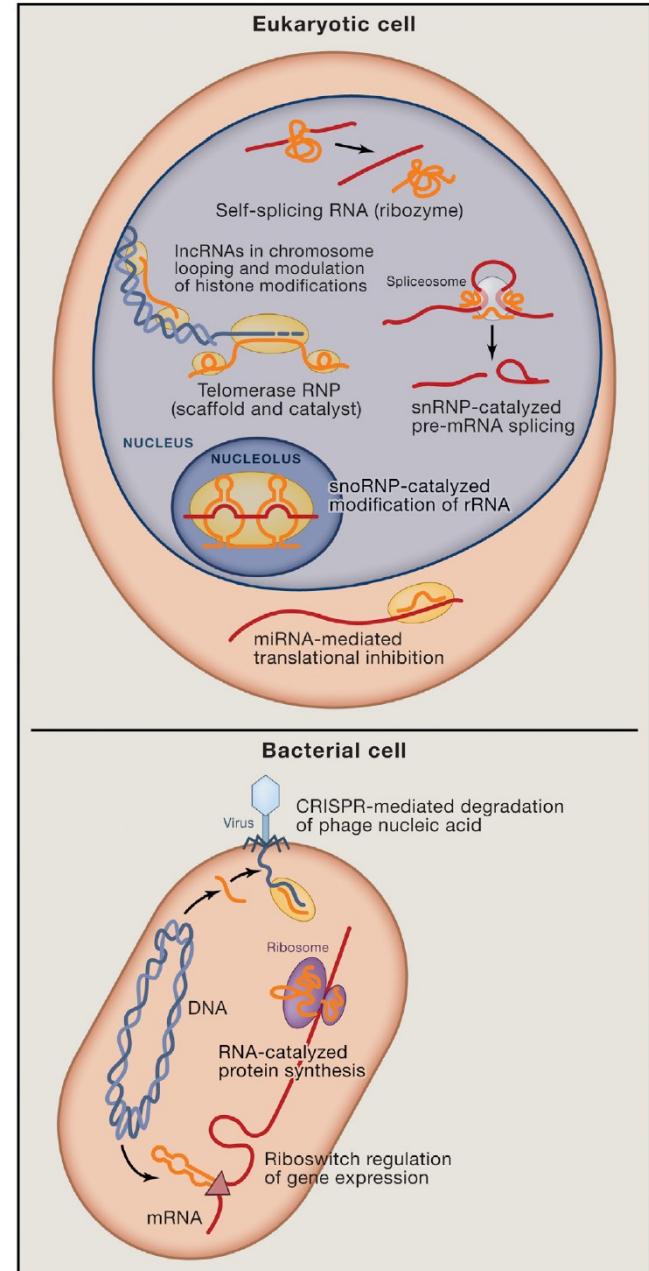

25 000

Alternative splicing, alternative promoters and post-translational modifications increase proteome complexity

RNA genes

- **genes for functional non-coding RNAs**
- Regulation of gene expressions
- Epigenetic inheritance
- Ribozymes (catalyze biochemical reactions)
- Possible remnants of RNA world

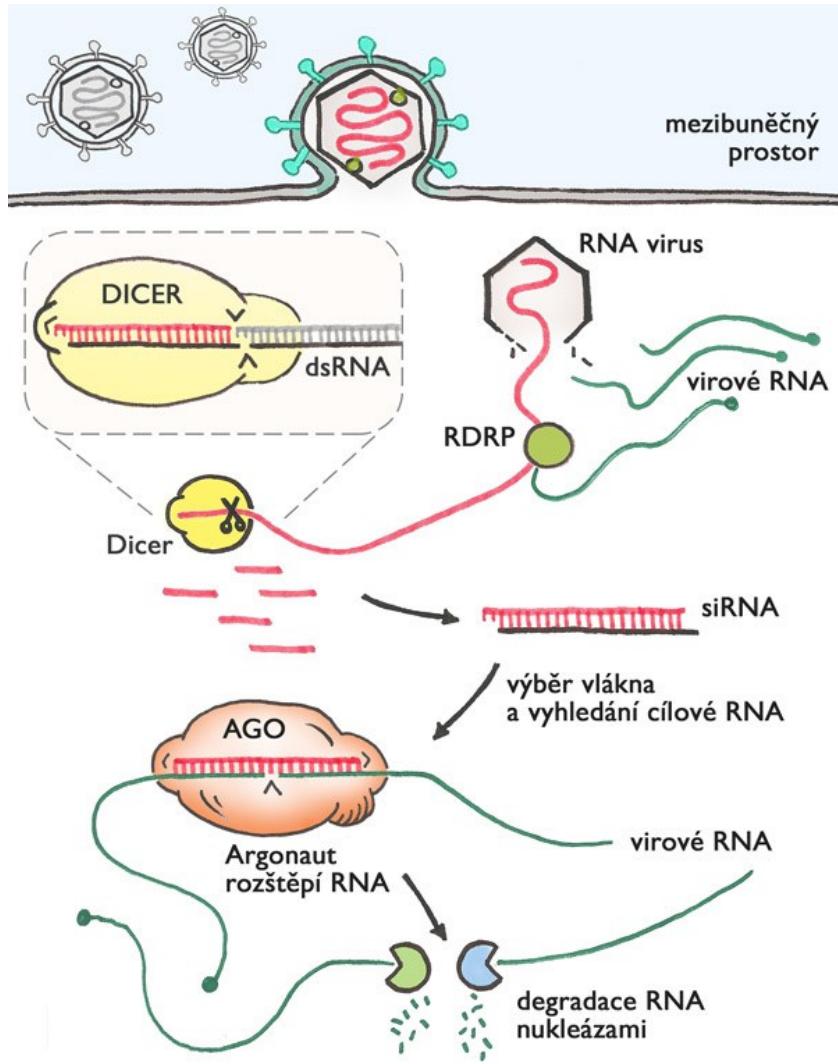

Small non-coding RNAs

- Usually shorter than 100 nt, regulatory ncRNA ~20-30 nt long
- Ribosomal RNA (rRNA)
- Transfer RNA (tRNA)
- Small nuclear RNA (snRNA)
- Small nucleolar RNA (snoRNA)

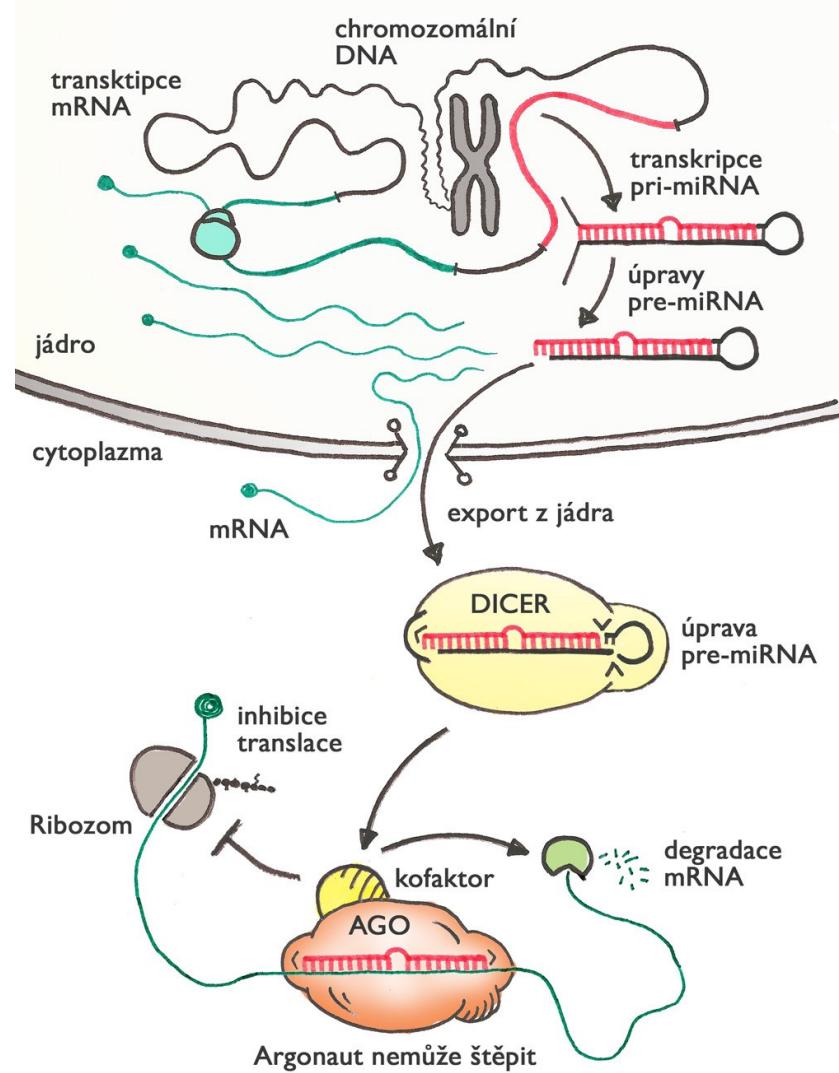

Regulatory RNA

- Small interfering RNA (siRNA) – defence against RNA viruses
- Micro RNA (miRNA) – regulation of gene expression
- Piwi interacting RNA (piRNA) – defence against transposons

siRNA

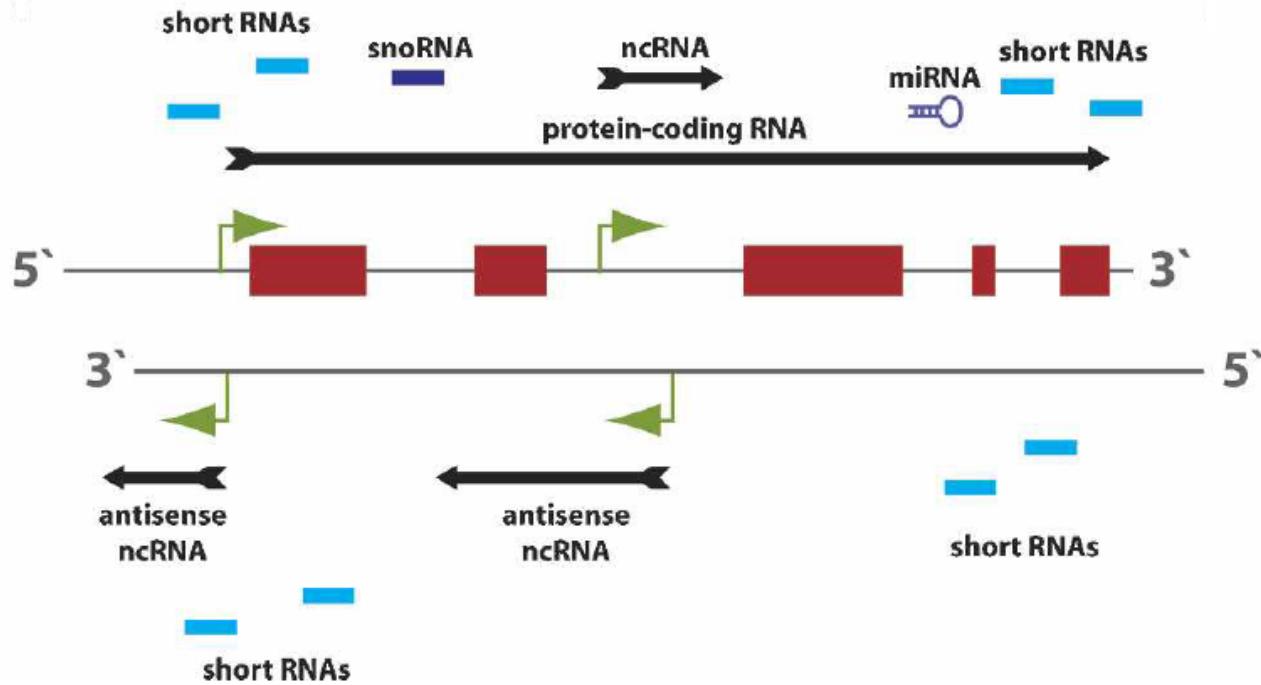

miRNA

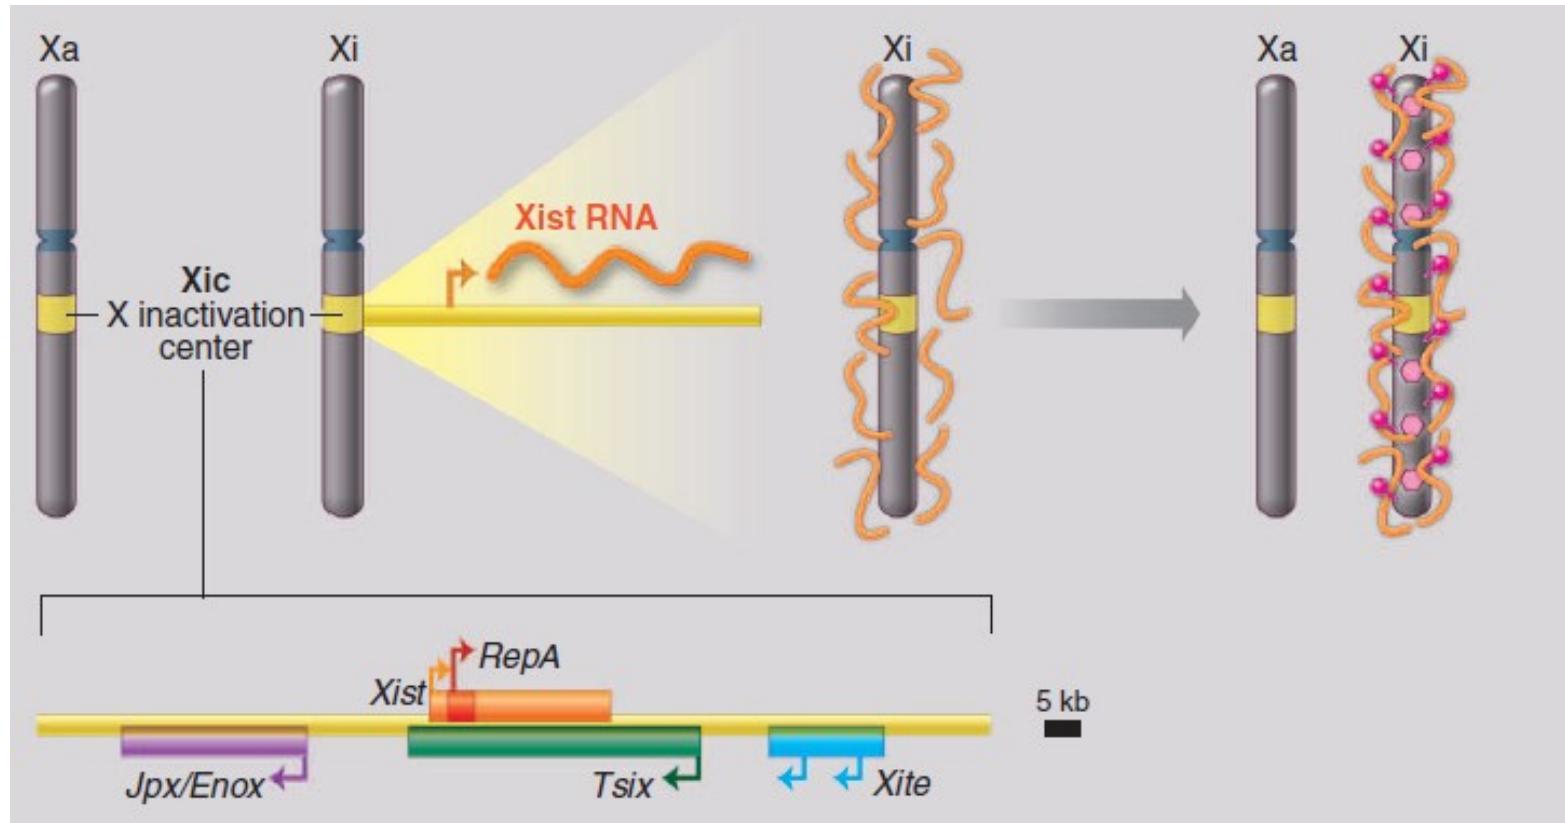

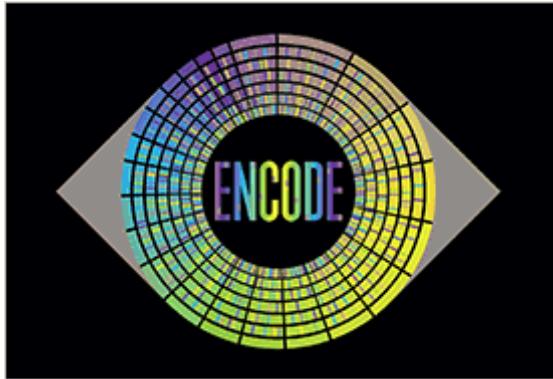

Long non-coding RNAs

- Usually longer than 100 nt
- Function of many of them unknown
- Often overlap with coding genes
- Regulation of gene expression

Xist non-coding RNA

ENCODE (Encyclopedia of DNA Elements)

a project which aims to identify functional elements in the human genome (protein coding genes, RNA genes, regulatory regions etc.)

ARTICLE

[doi:10.1038/nature11247](https://doi.org/10.1038/nature11247)

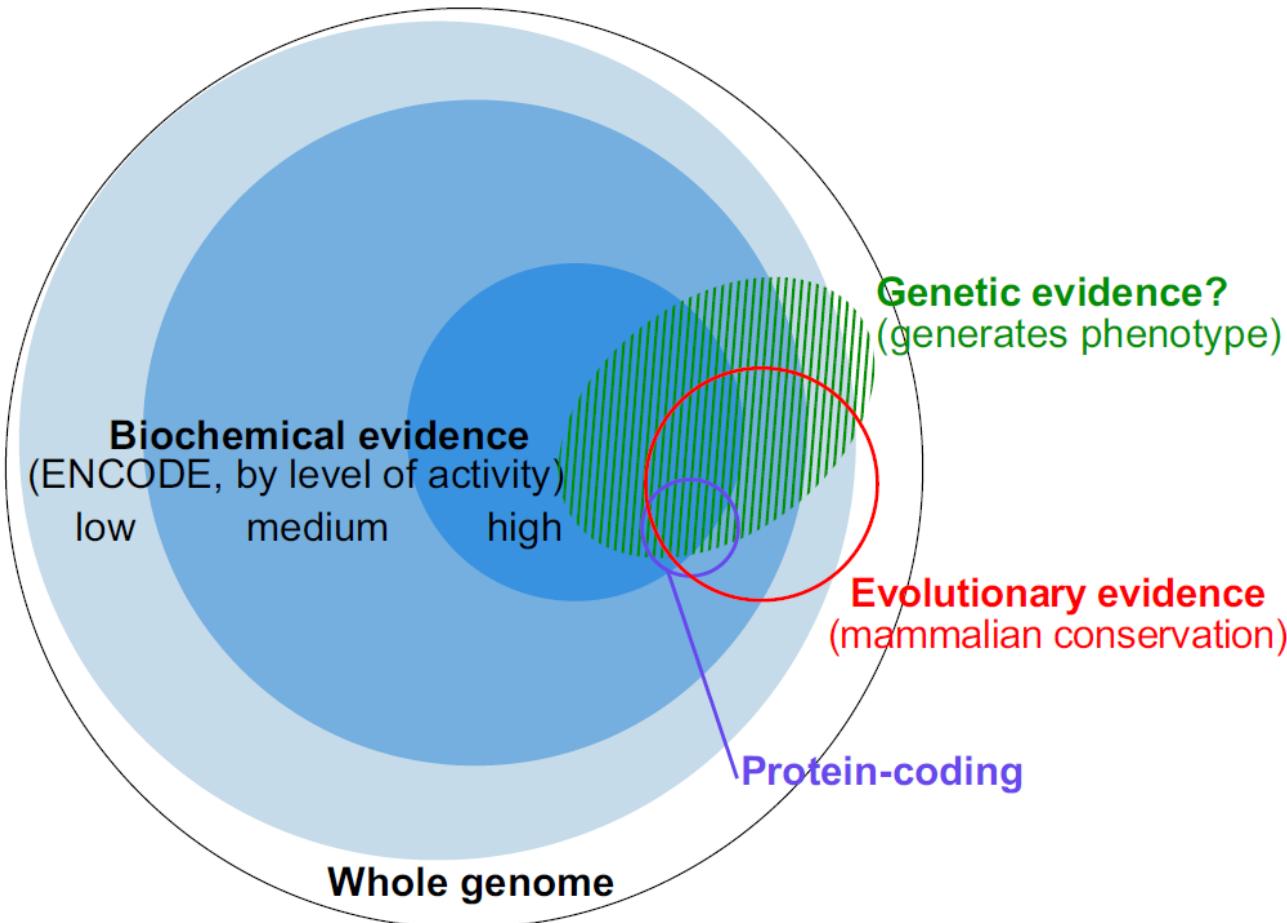

An integrated encyclopedia of DNA elements in the human genome

The ENCODE Project Consortium*

6 SEPTEMBER 2012 | VOL 489 | NATURE | 57

- **about 80% genome is transcribed**

What fraction of human genome is functional?

Pseudogenes

- Nonfunctional gene copies (shortened, premature stop-codons, usually not transcribed)
- In the human genome ~ 14 000 pseudogenes (13% transcriptionally active).

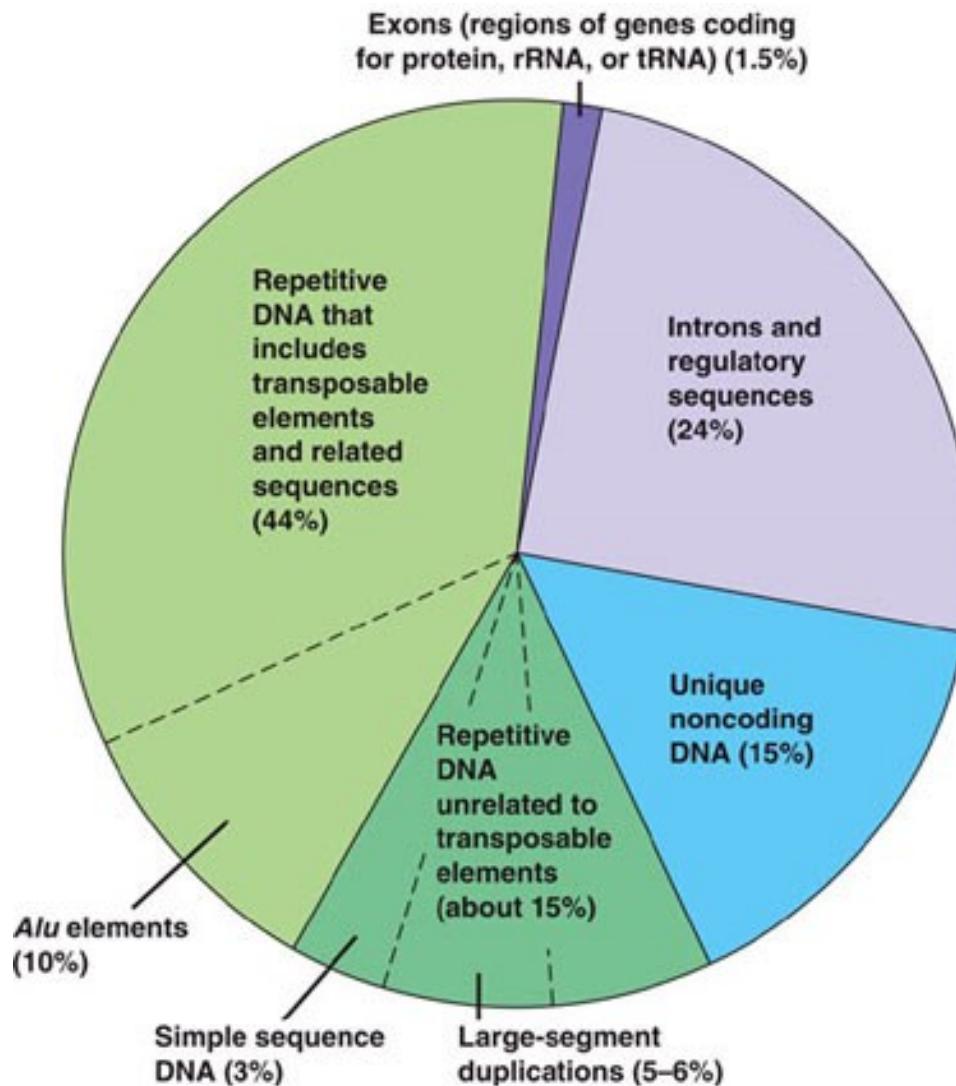

Nonprocessed pseudogenes

Originate by genome duplication. Contain exons and introns, often also surrounding sequences including promoters.

Processed pseudogenes

Originate by reverse transcription of mRNA. No introns, polyA.

Composition of human genome

„junk“ DNA

Repetitive sequences

Tandem repeats

microsatellites – repeat motif 1-6 bp long (e.g. CACACACA.....)

minisatellites – repeat motif up to 25 bp, e.g. telomeric sequences

satellites – repeat motif several hundreds bp long or even longer,
e.g. centromeric sequences

Repetitive sequences

Mobile DNA elements (transposable elements)

DNA transposons – move by transposition through DNA molecule

retrotransposons – move by retrotransposition through RNA molecule

DNA transposons

- Code an enzym **transposase**.
- Sometimes additional genes (e.g. genes for resistance to antibiotics in bacteria)
- IS elements and Tn elements in prokaryotes.
P elements in Drosophila.
Ac a Ds elements in corn (Barbara McClintock).

<p><u>1. LTR retrotransposons

- Originated from retroviruses.
- Long terminal repeats (LTR) contain regulatory sequences, promoters.
- Code enzyme **reverse transcriptase**.
- In *Vicia faba* cca 1 million copies of element Ty1-copia (half of the genome).

Ty1-copia, Ty3-copia

- Similar structure have **endogenous retroviruses**. Remnants of ancient once infectious exogenous retroviruses.

LTR ... dlouhé koncové řetězce
PBS ... místo vazby primeru
PR proteáza
INT integráza
RT reverzní transkriptáz
PPT polypurinový úsek
▶ přímé řetězce

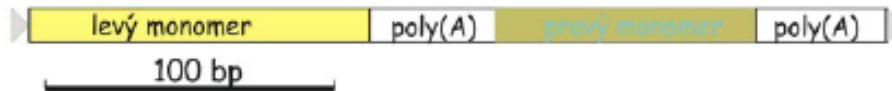

nonLTR retrotransposons

- Do not have LTR. Poly(A) on 3' end.
- Most common transposons in mammals, including human.
- **LINE (Long interspersed nuclear elements)**
Code its own reverse transcriptase.
- **SINE (Short interspersed nuclear elements)**
Do not have its own transcriptase.
Their movement dependent on the presence of LINE elements.
- **Alu sequence (SINE):** the most common transposon in humans (1,5 million copies, 13% of the genome). Originated from a gene coding tRNA 7SLRNA

(c) LINE (L1):

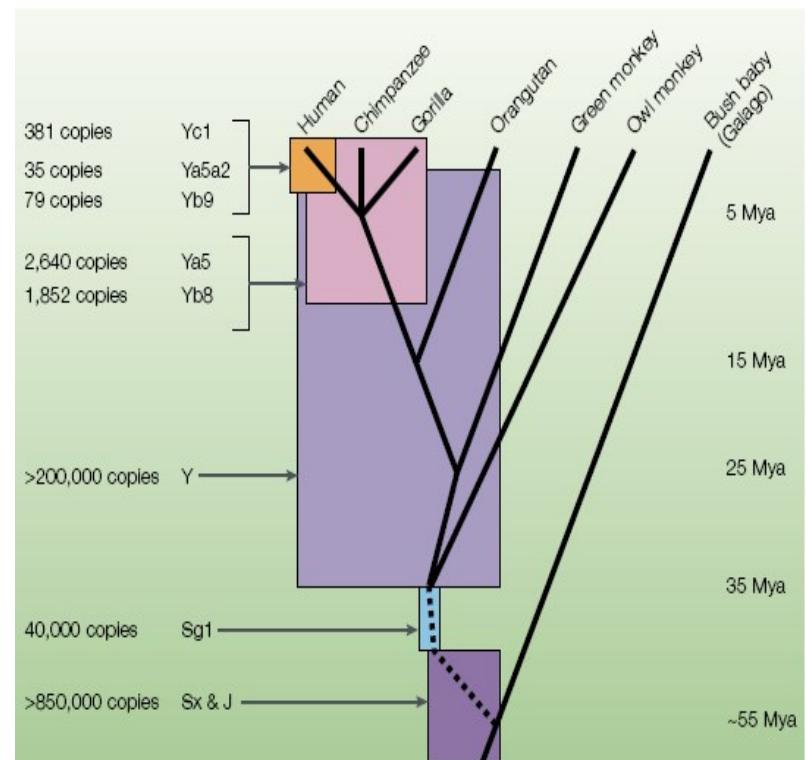

(d) SINE (sekvence Alu):

Evolution of transposable elements

- Periods of TE activity and silence.
- Most TE in the genome are shortened and non-functional. But can be copied if there are at least some functional TEs providing enzymes.
- Relatively frequent horizontal gene transfer.

The expansion of Alu subfamilies
(Nat Rev Genet)

Negative effects of TEs

Increase in the genome size

- 3-45% of the genome in animals.
Up to 80% of the genome in plants (corn)
- Higher energetical demands for the cell.
- Enlargement of the cell.

Giant genomes of salamanders

- Genome size ~120 Gb.
Large amount of LTR retrotransposons.
- Increased cell size.
- Simplification of nervous and a optical system.
- Some species have red blood cells without the nucleus.
- Some species have only four fingers on the legs.

Increase in the mutation rate

- **Insertion mutagenesis.**
- **Alteration of gene expression of nearby genes.**
- **Ectopic recombination**

- To prevent movement of TEs in the genome, organisms heterochromatinize the genomic regions containing TEs.
- Important role of piwi RNAs.

Positive effects of TEs

Regulation of mutation rate in response to stress

- Stress conditions (UV or gamma radiation, infection by patogen, injury, change of temperature...) can lead to TE activation.
- Increased mutation rate can lead to new adaptations.

Tam1 , Tam3 u hledíku
(1000x větší aktivita při 15°C)
Reme1 u melounu (aktivace UV)

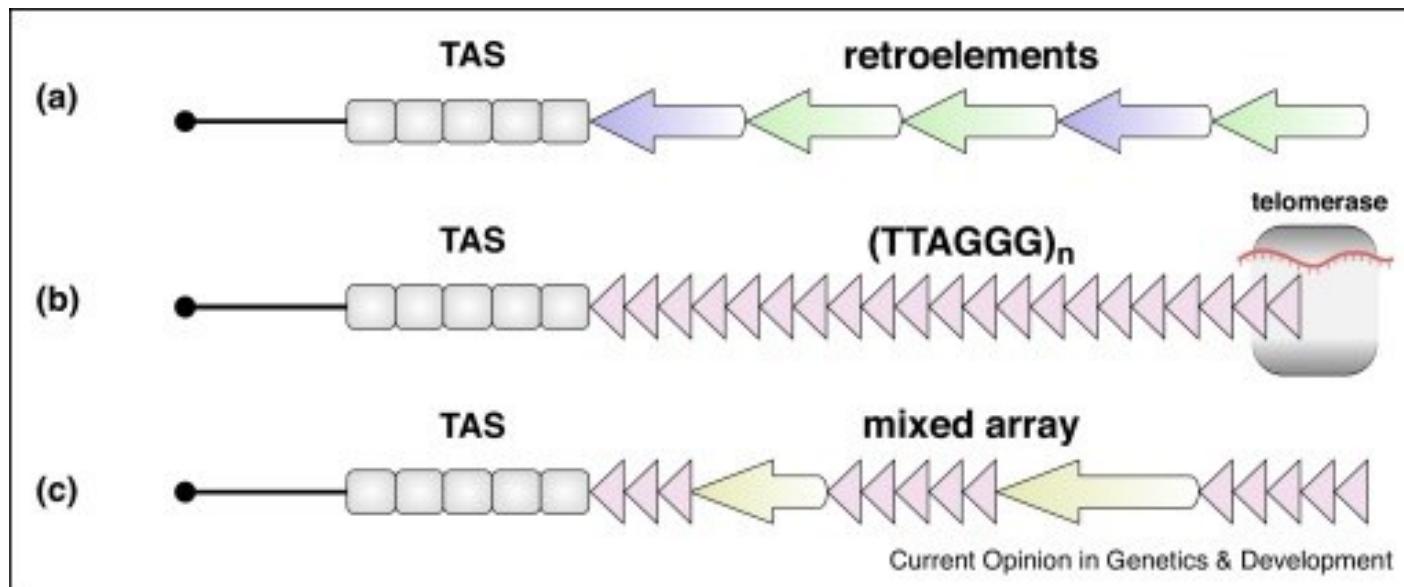

TEs make genome more dynamic

- Gene duplications.
- Structural changes (translocations, inversions)
- „Exon shuffling“ (Helitrons).

Helitrons = DNA transposons, transpose by a rolling circle replication mechanism. Can move parts of genes. Creation of new chimeric genes.

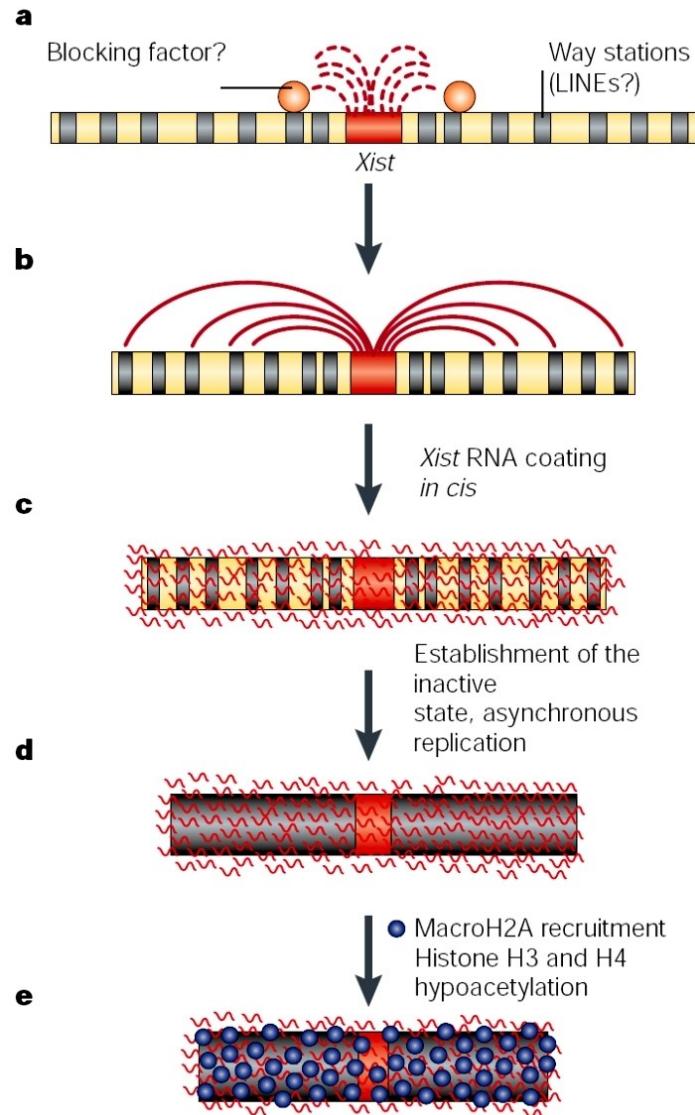

Molecular domestication of TEs

- Retrotransposons make up **telomeres** in *Drosophila melanogaster* (non-LTR retrotransposons Het-A, TART, TAHRE). Telomere elongation is achieved by TE retrotransposition.

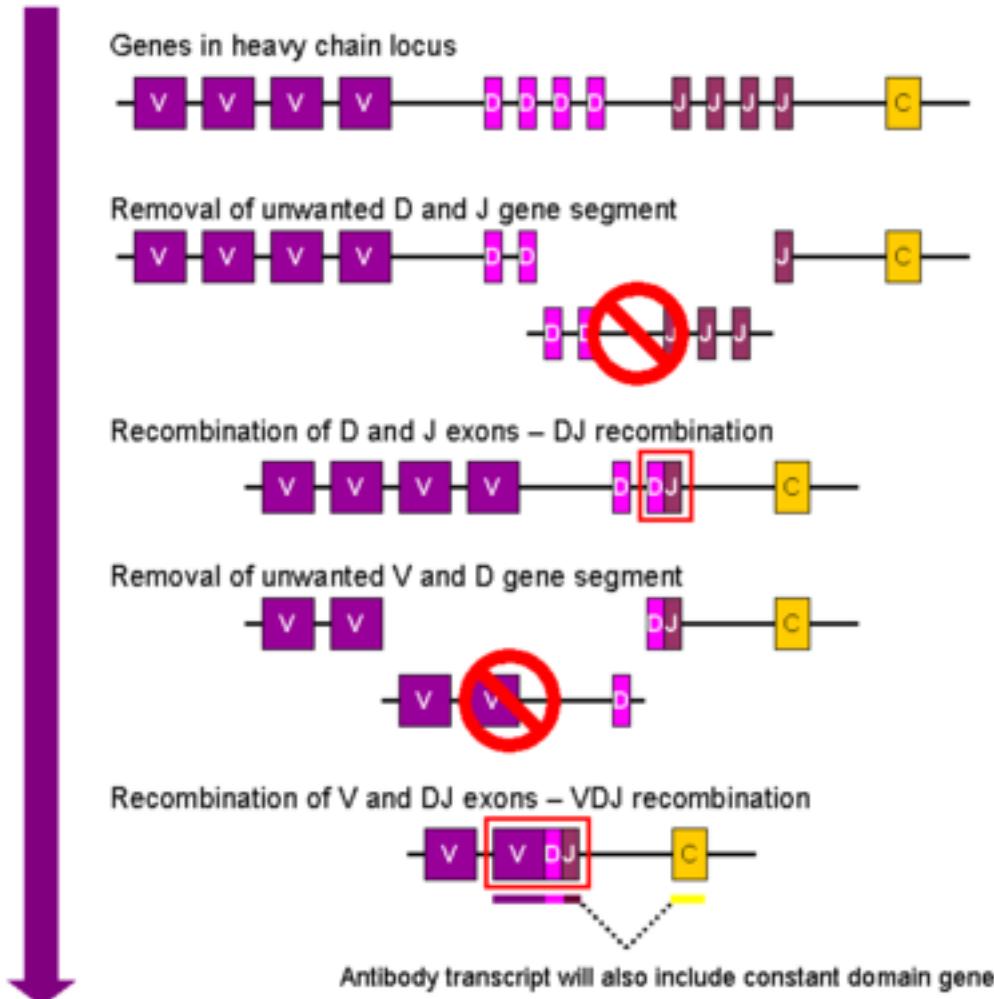

Formation of heterochromatin

- TEs often silenced by heterochromatinization.
- They sometimes make an important part of centromeric heterochromatin.
- LINE elements play a role in inactivation of the X chromosome in female somatic cells in mammals.

V(D)J recombination in immunoglobulins

Important role of RAG proteins. Derived from transposase.

Industrial melanism in the Peppered moth

The dark form (carbonaria) originated in the 1. half of the 19. century (industrial revolution) by insertion of TE to the vicinity of cortex gene, which increased its expression.

van't Hof, A. et al. 2016.

Syncytin – derived from env from endogenous retrovirus HERV –W.
Important role in placenta development in mammals and viviparous lizards.

Origin of large evolutionary innovations

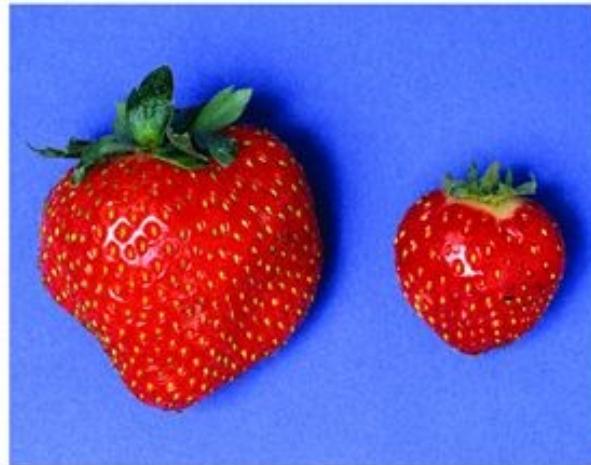

- Simultaneous change of gene expression of many genes.

Cell Reports, 2015

Polyploidization

- Common especially in plants (60–70% angiosperms are polyploids).
- Problems with meiosis. Often transition to asexual reproduction.
- Functional redundancy, can enhance adaptive evolution.

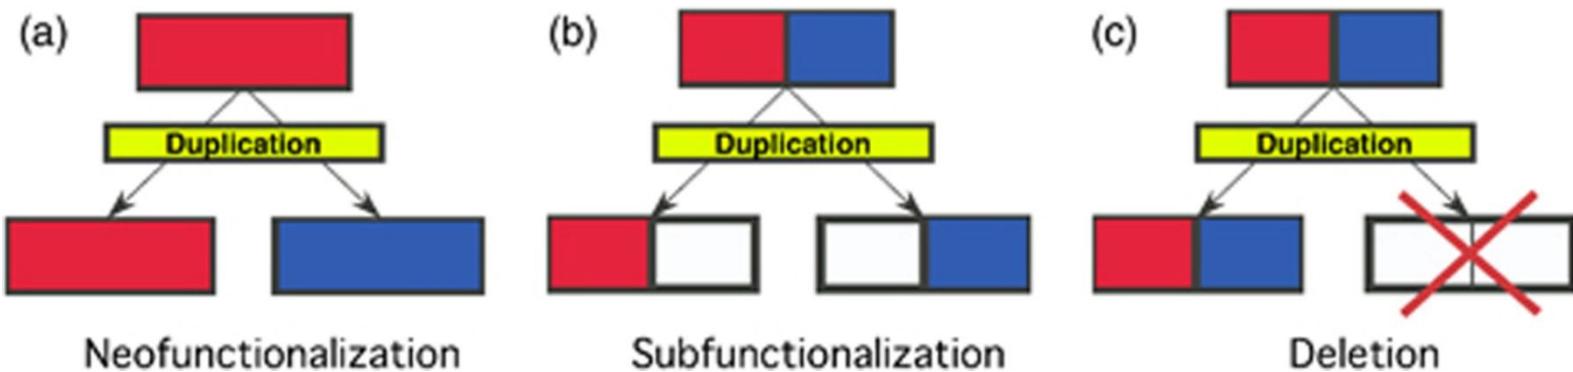

(a) Octaploid strawberries (left)
and diploid strawberries (right)

(b) Diploid daylilies (left)
and tetraploid relative (right)

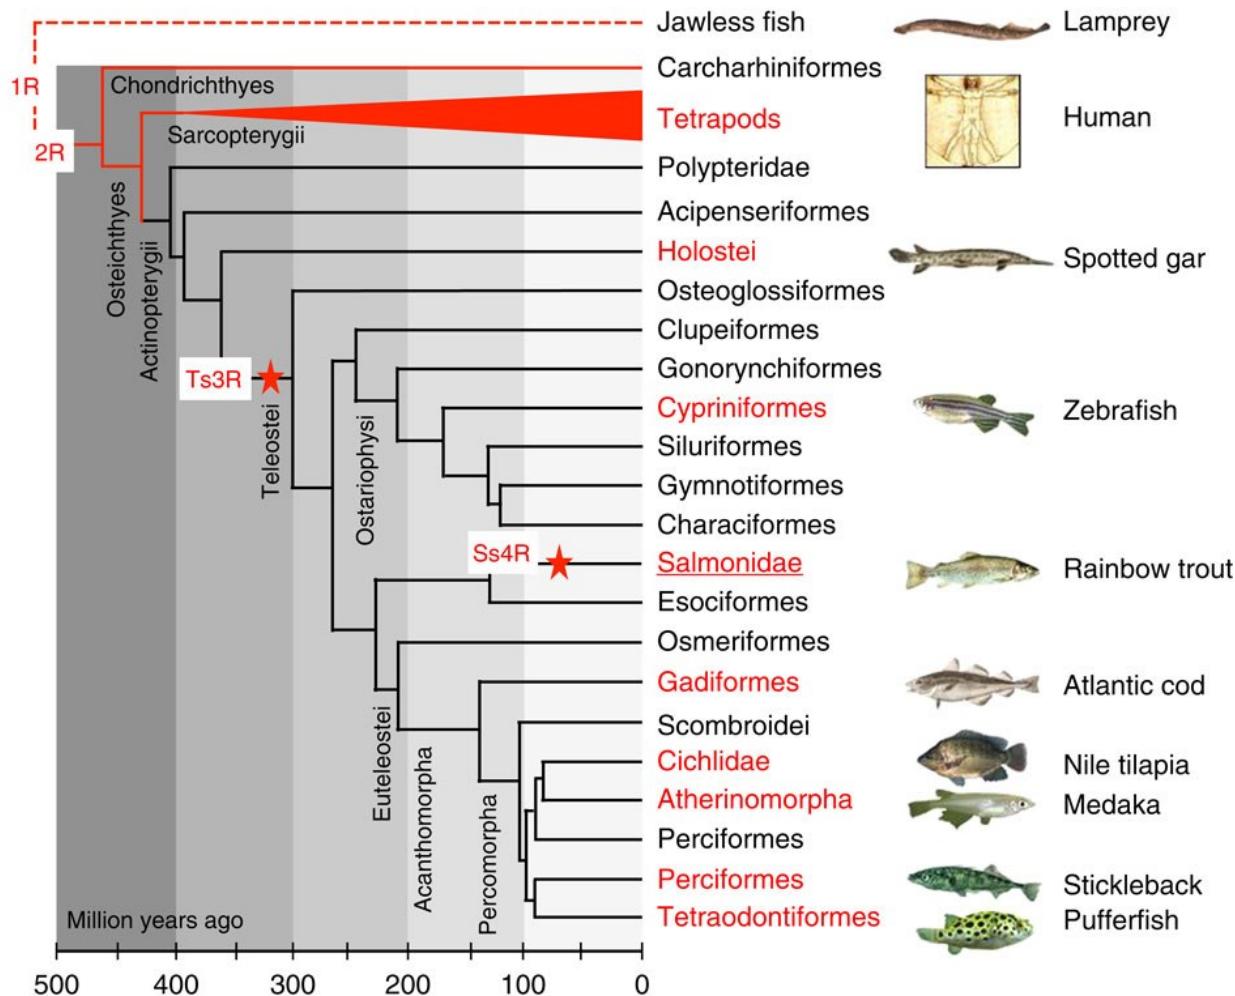

Duplications

- Faster adaptive evolution.
- Evolution of reproductive isolation (loss of different copies in different populations can result in sterility or inviability of hybrids). Can speed up speciation.

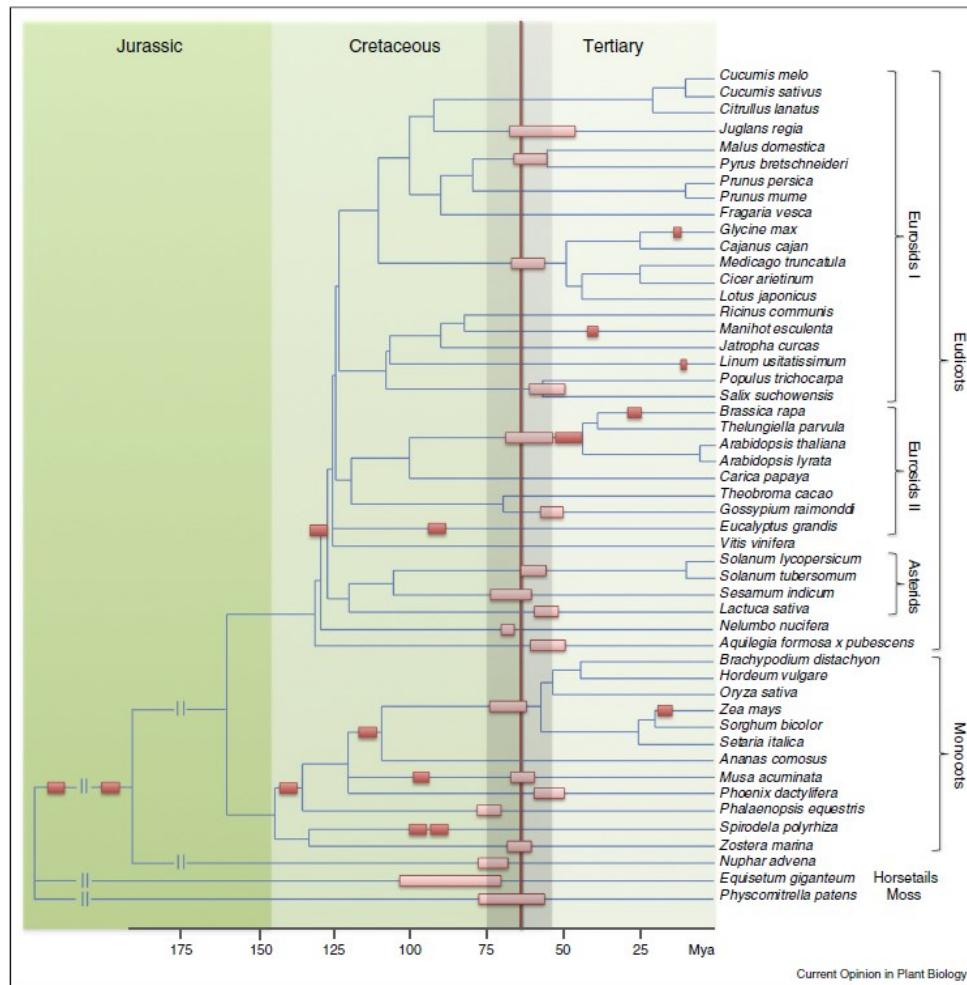

Paleopolyplody in vertebrates

- 2 in the ancestor of all vertebrates.
- 1 in the ancestor of Teleostei.
- 1 in Salmonidae fish.

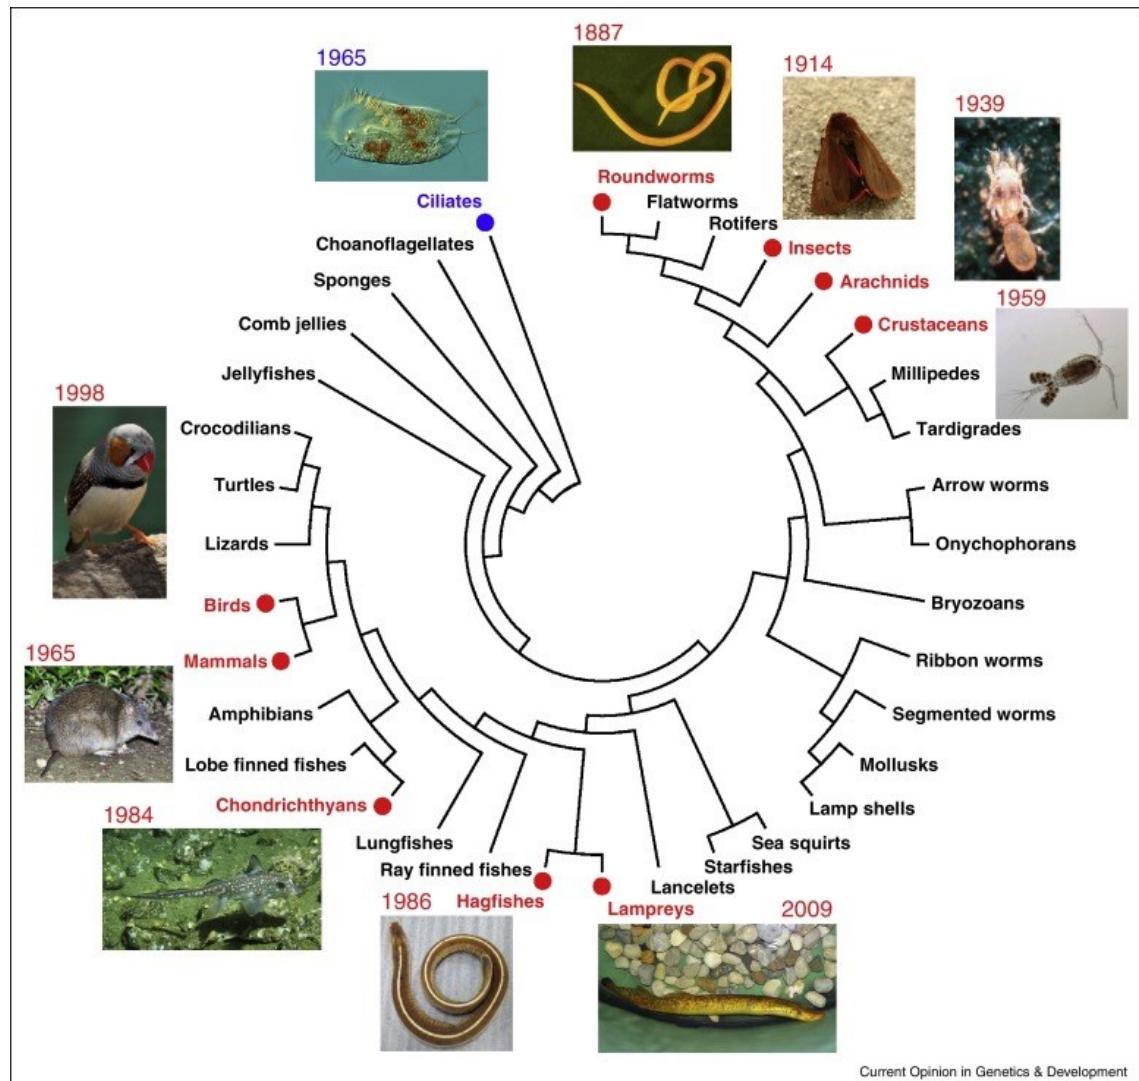

Paleopolyplody in angiosperms

- Relatively more whole genome duplications close to K-T boundary. Polyplloid plants might better survived in markedly changed environments compared to diploids.

Programmed DNA elimination

Elimination of parts of the genome from some or all somatic cells.

Genome as ecosystems

- Genes and other functional elements as species.
- Alleles of genes as individuals of particular species (compete over reproduction, „selfish genes“)
- Interactions among genes (parasitism, mutualism). Intergenomic conflicts.
